

PSOMAS

2015 PAG LiDAR Data Accuracy Assessment

Pima Association of Governments

Pima County Regional Flood Control District

2015 PAG LiDAR Data Accuracy Assessment

Prepared by Psomas

Project No. 7PIM130303

July 30, 2015

Introduction

In December of 2014 Psomas was contracted by the Pima County Regional Flood Control District to provide the Elevation Data Horizontal and Vertical Accuracy Assessment for the Pima Association of Governments 2015 LiDAR and Aerial Imagery acquisition. Psomas has a long and distinguished history of surveying in Pima County and welcomed the opportunity to participate in this vital local project.

Project Description

The main project area is comprised of approximately 2,203 square miles of eastern Pima County and a smaller area of 36 square miles located in the northeast corner of the County. The LiDAR data was acquired in March of 2015 by Sanborn Map Company using a Leica ALS70 Airborne Laser Scanner. The project horizontal datum is Arizona State Plane, Central zone, NAD83 (2011), epoch 2010.0, with units in International Feet. The vertical datum is NAVD88. Orthometric heights (elevations) were derived from ellipsoid heights using a high resolution geoid model, Geoid12A. The data acquisition was designed to comply with the requirements for QL2/QL3 LiDAR accuracy as stated in the USGS Survey Standards, Chapter 4 of Book 11, LiDAR Base Specifications for inclusion in the USGS 3DEP program. This report primarily deals with the absolute vertical accuracy of Non-Vegetated LiDAR coverage, and a limited subset of points to estimate horizontal accuracy.

Methodology

Pima County, and the metro Tucson area in particular, has a well-established geodetic control network. Recent surveys by local agencies have densified the control and provided an opportunity to evaluate this data, as well new check points collected specifically for this project. The quantity and location of check points was designed to meet the recommendations in the Positional Accuracy Standards for Digital Geospatial Data as published by the American Society for Photogrammetry and Remote Sensing (ASPRS) 2014 (see Figure 1). All new check points were collected in open, flat areas, such as parking lots, school yards, and parks. In rural areas the check points were positioned on flat, open areas away from trees and dense vegetation. All of the urban environment and a majority of the rural areas are classified as Non-vegetated. A small portion of the project in the extreme southeast corner is at higher elevation and could be classified as Vegetated depending on the amount of seasonal rainfall and native grass growth in the spring. A total of 274 points were selected for this project, comprised of 132 new check points and 142 control points included from existing sources. A list of the check points can be found in Appendix A.

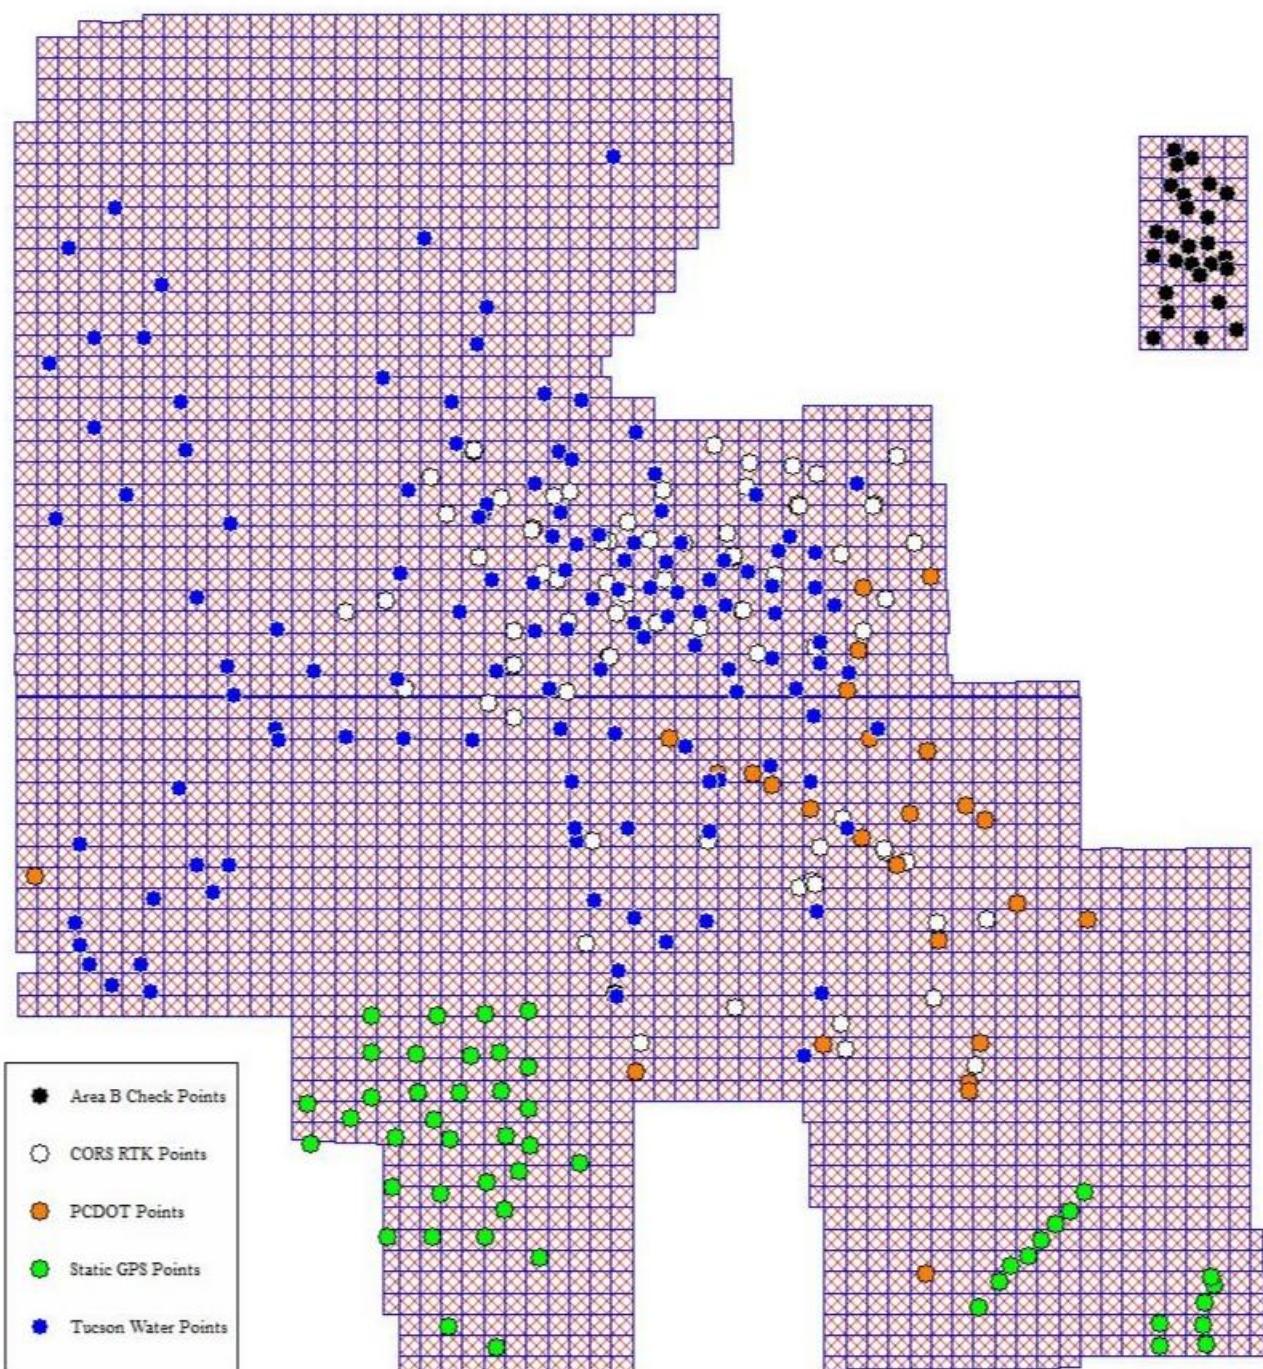

Figure 1

QL2/QL3 Check Point Distribution

The check points can be classified into 4 groups that reflect the Survey method used to collect the location and elevation: Static GPS, RTK GPS, CORS RTK, and OPUS GPS. The following describes each method in more detail.

- 1) Static GPS points: these check points were collected and post-processed to FGDC local network accuracy standards. Primarily used in areas of the coverage that lack existing survey control and/or validation points. The minimum occupation time was 30 minutes per point and at least 2 CORS stations vector ties to each point. Points were then post-processed in Trimble Business Center to the 95% confidence level. Points used for RTK base stations were double occupied and submitted to OPUS for further validation.
- 2) GPS RTK points: Supplemental check points on structures and identifiable objects. These points were collected using a traditional GPS Real Time Kinematic (RTK) base-rover methodology.
- 3) CORS RTK points: random points collected from single base line RTK solution using the nearest AZCORS station. These points were collected at sites that offered an open expanse and varied surfaces, such as school playgrounds, parks, large parking lots, and open terrain.
- 4) Tucson Water geodetic points: existing survey monuments located at various well sites throughout the area. These points were collected in Static mode and processed using OPUS. All of these points involved multiple observations and additional verification by Tucson Water surveyors.
- 5) Pima County DOT OPUS points: randomly distributed points collected in Static mode and processed using OPUS. Most are 2 hour single occupations and are focused mainly on local survey control, benchmarks, and random points on highly identifiable objects.

Vertical Accuracy Assessment

The vertical accuracy assessment was performed using Applied Imagery's Quick Terrain Modeler program. A list of tiles was generated by evaluating the check point locations against the tile index. This list was used to load the corresponding LAS files into QT Modeler. The check points were loaded into the Point Query Utility which compares the elevation of the points to elevations in the model. QT Modeler then creates a TIN surface at each point to calculate the surface elevation and reports the elevation differences. The method used is in compliance with standards for establishing RMSE and quality control of LIDAR surveys. The output from the Point Query Utility was converted to an MS Excel file for further computational analysis. Fourteen (14) points were eliminated as outliers and removed from the analysis. The results can be found in Appendix B.

Results of the Absolute Vertical Accuracy Assessment

Per the project specifications the absolute vertical accuracy for Quality Level 2 is ≤ 10 cm, or ≤ 19.6 cm at the 95% confidence level. The subset of 132 newly collected check points yielded an RMSE_z of 9.7 cm. The entire combined set of 260 check points resulted in an RMSE_z = 9.76 cm.

This data set was tested to meet ASPRS Positional Accuracy Standards for Digital Geospatial Data (2014) for a 10 cm RMSE_z Vertical Accuracy Class. Actual NVA accuracy was found to be RMSE_z = 9.76 cm, equating to ± 19.13 cm at 95% confidence level. No assessment of the VVA accuracy is included due to the lack of qualifying land cover areas.

Horizontal Accuracy Assessment

Horizontal error in LiDAR is mainly a function of the position and attitude errors at the sensor, and the flying height. An estimate of the horizontal error can be made assuming the positional, attitudinal, and height accuracies are known. This error estimate comes from the LiDAR provider and per the ASPRS Positional Accuracy Standards for Digital Geospatial Data (2014) those values are:

GNSS Positional Error= 2cm

IMU Error= 0.5°

Mean Flying Height= 3,200m

From this the estimated horizontal positional error is calculated to be 0.50 cm.

Well defined points typically used for checking planimetric accuracies in topographic mapping and orthophotography may not be appropriate for LiDAR analysis. For this project we collected a small number of check points that fell at the end of paint stripes and other high contrast features for use as horizontal checks. Most of the rural areas within the coverage did not contain adequate features for horizontal assessment. In the smaller area we were able to collect the deck of 2 bridges for comparison the LiDAR data. Unfortunately the LiDAR point spacing did not provide enough density to make exact measurement of these features and no definable assessment of the horizontal accuracy can be made with this methodology.

This report is based upon field work and office calculations performed under my direct supervision.
