## List of Appendices

- Appendix A: GPS / IMU Processing Statistics, Flight Logs, and Base Station Logs  
 Appendix B: Survey Report

## 1. Summary / Scope

### 1.1. Summary

This report contains a summary of the Connecticut River Watershed / Winnipesaukee River Watershed / White Mountain National Forest 2015 LiDAR acquisition task order, issued by USGS National Geospatial Technical Operations Center (NGTOC) under their Geospatial Products and Services Contract proposed on August 1, 2015 and modified on November 9, 2015. The task order yielded a project area covering 5,233 square miles that includes several areas of interest in New Hampshire. The intent of this document is only to provide specific validation information for the data acquisition/collection, processing, and production of deliverables completed as specified in the task order.

### 1.2. Scope

Aerial topographic LiDAR was acquired using state of the art technology along with the necessary surveyed ground control points (GCPs) and airborne GPS and inertial navigation systems. The aerial data collection was designed with the following specifications listed in Table 1 below.

Table 1. Originally Planned LiDAR Specifications

Average Point Density	Flight Altitude (AGL)	Field of View	Minimum Side Overlap	RMSEz
≥ 2 pts / m <sup>2</sup>	2,000 - 3,000 m	40°	30%	≤ 10 cm

### 1.3. Coverage

The modified LiDAR project boundaries consist of 3 areas of interest: 4,437 square miles over the Connecticut River watershed, 796 square miles over the Winnipesaukee River Watershed, and 181 square miles over portions of the White Mountain National Forest (WMNF) in New Hampshire for a total of 5,233 square miles (there is some overlap with these areas of interest). A processing boundary of 100-meters was created for this area. LiDAR extents are shown in Figure 1 on the following page.

### 1.4. Duration

LiDAR data was acquired from October 24, 2015 to November 23, 2015 in 29 total lifts. See “Section: 2.5. Time Period” for more details.

## 1.5. Issues

There were no issues to report with this project.

## 1.6. Deliverables

The following products were produced and delivered for the Connecticut and Winnipesaukee River Watershed AOIs:

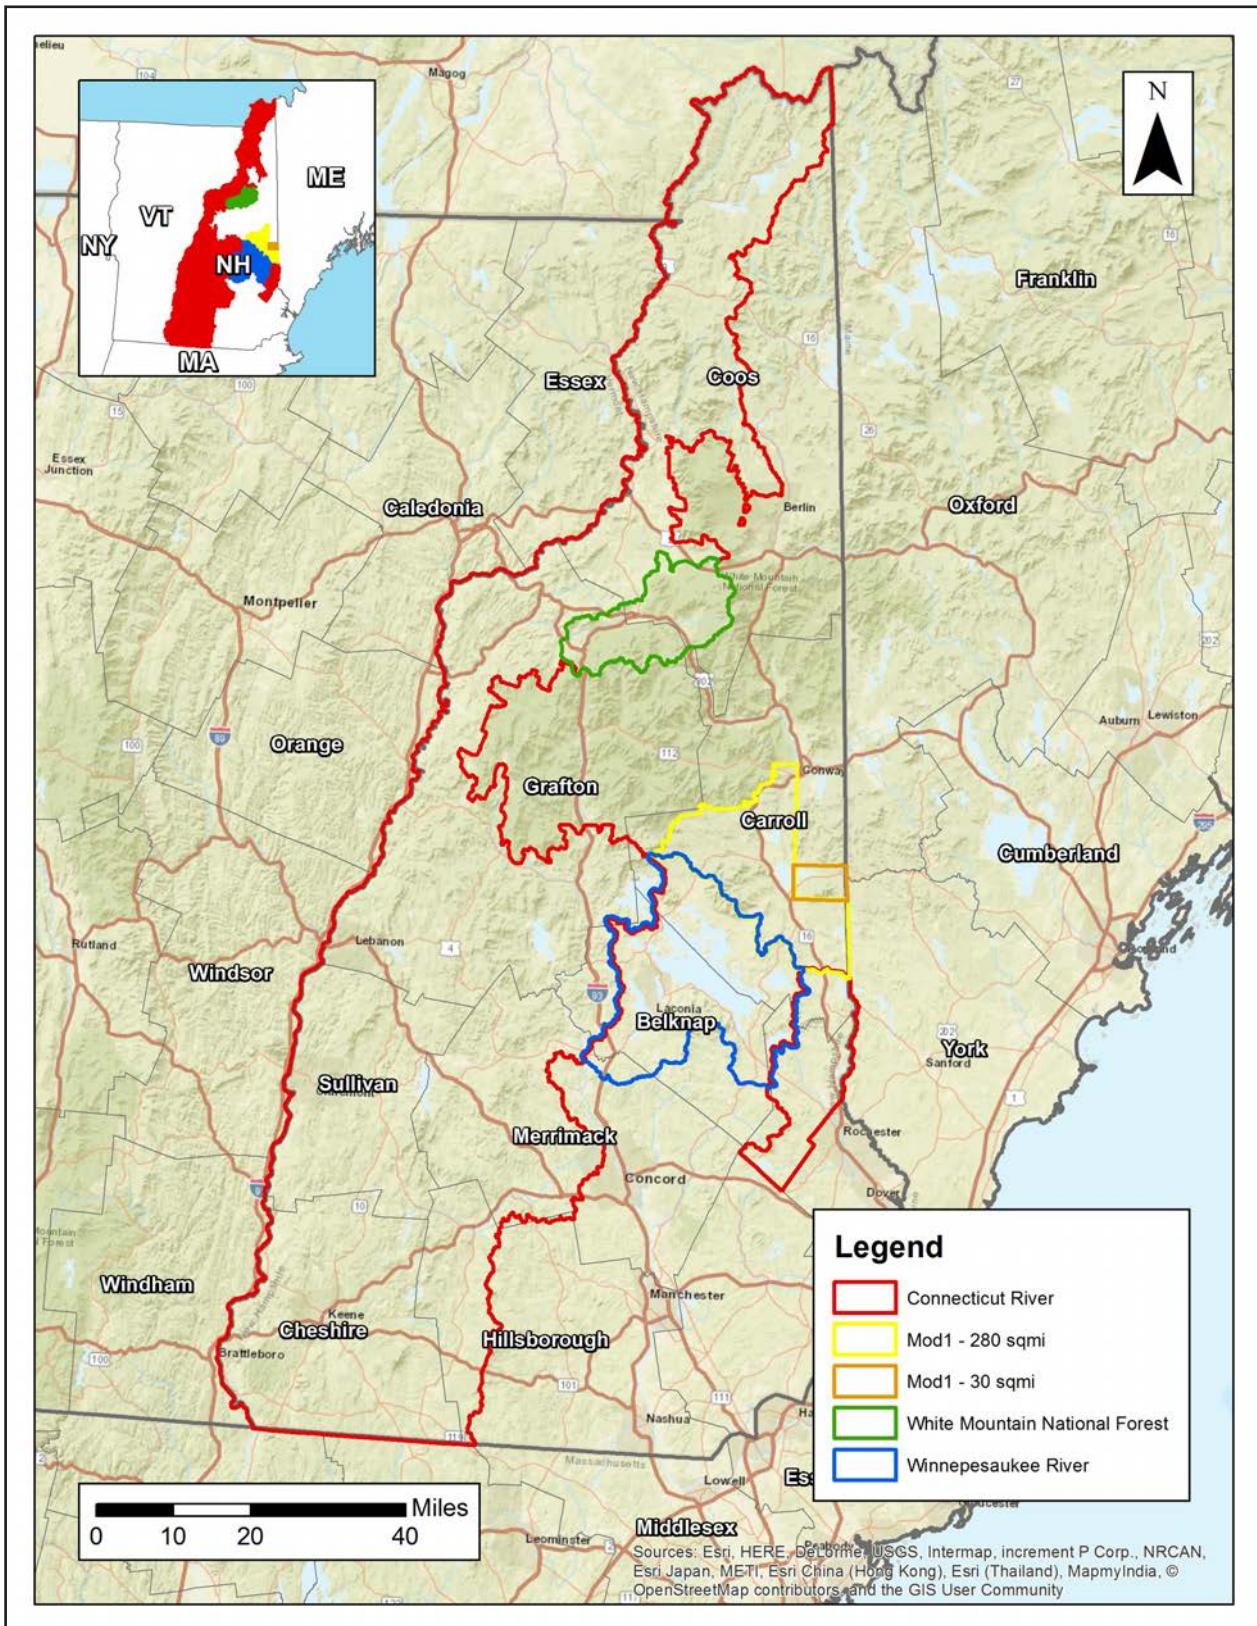

- Raw LiDAR point cloud data swaths in LAS 1.4 format
- Classified LiDAR point cloud data, tiled, in LAS 1.4 format
- 1-meter hydro-flattened bare-earth raster DEM, tiled, in GeoTIFF format
- 1-meter hydro-flattened bare-earth raster DEM mosaic in GeoTIFF format
- Hydro-flattened breaklines in Esri file geodatabase format
- Calibration and QC checkpoints in Esri shapefile format
- 1-meter intensity image, tiled, in GeoTIFF format
- QA/QC reports in Excel .XLS format
- Processing boundary in Esri shapefile format
- Tile index in Esri shapefile format
- Flightline swaths in Esri shapefile format
- Project-, deliverable-, and lift-level metadata in .XML format

The following products were produced for the White Mountain AOI:

- Raw LiDAR point cloud data swaths in LAS 1.4 format
- Classified first and last LiDAR data, tiled, in LAS 1.4 and ASCII comma-delimited formats

All geospatial deliverables for the Connecticut River and Winnepeaukee project areas were produced in NAD83 (2011) UTM Zone 19, meters; NAVD88 (Geoid 12B), meters. Tiled deliverables have a tile size of 1,500-meters x 1,500-meters with tile names based on the US National Grid.

A secondary set of deliverables for the White Mountain National Forest project area were produced in NAD83 (2011) UTM Zone 19, meters; NAVD88 (Geoid 12B), meters. Tiled deliverables have a tile size of 2,000 meters x 2,000 meters, and follow the existing WMNF naming schema.

**Figure 1. Project Boundary**

## 2. Planning / Equipment

### 2.1. Flight Planning

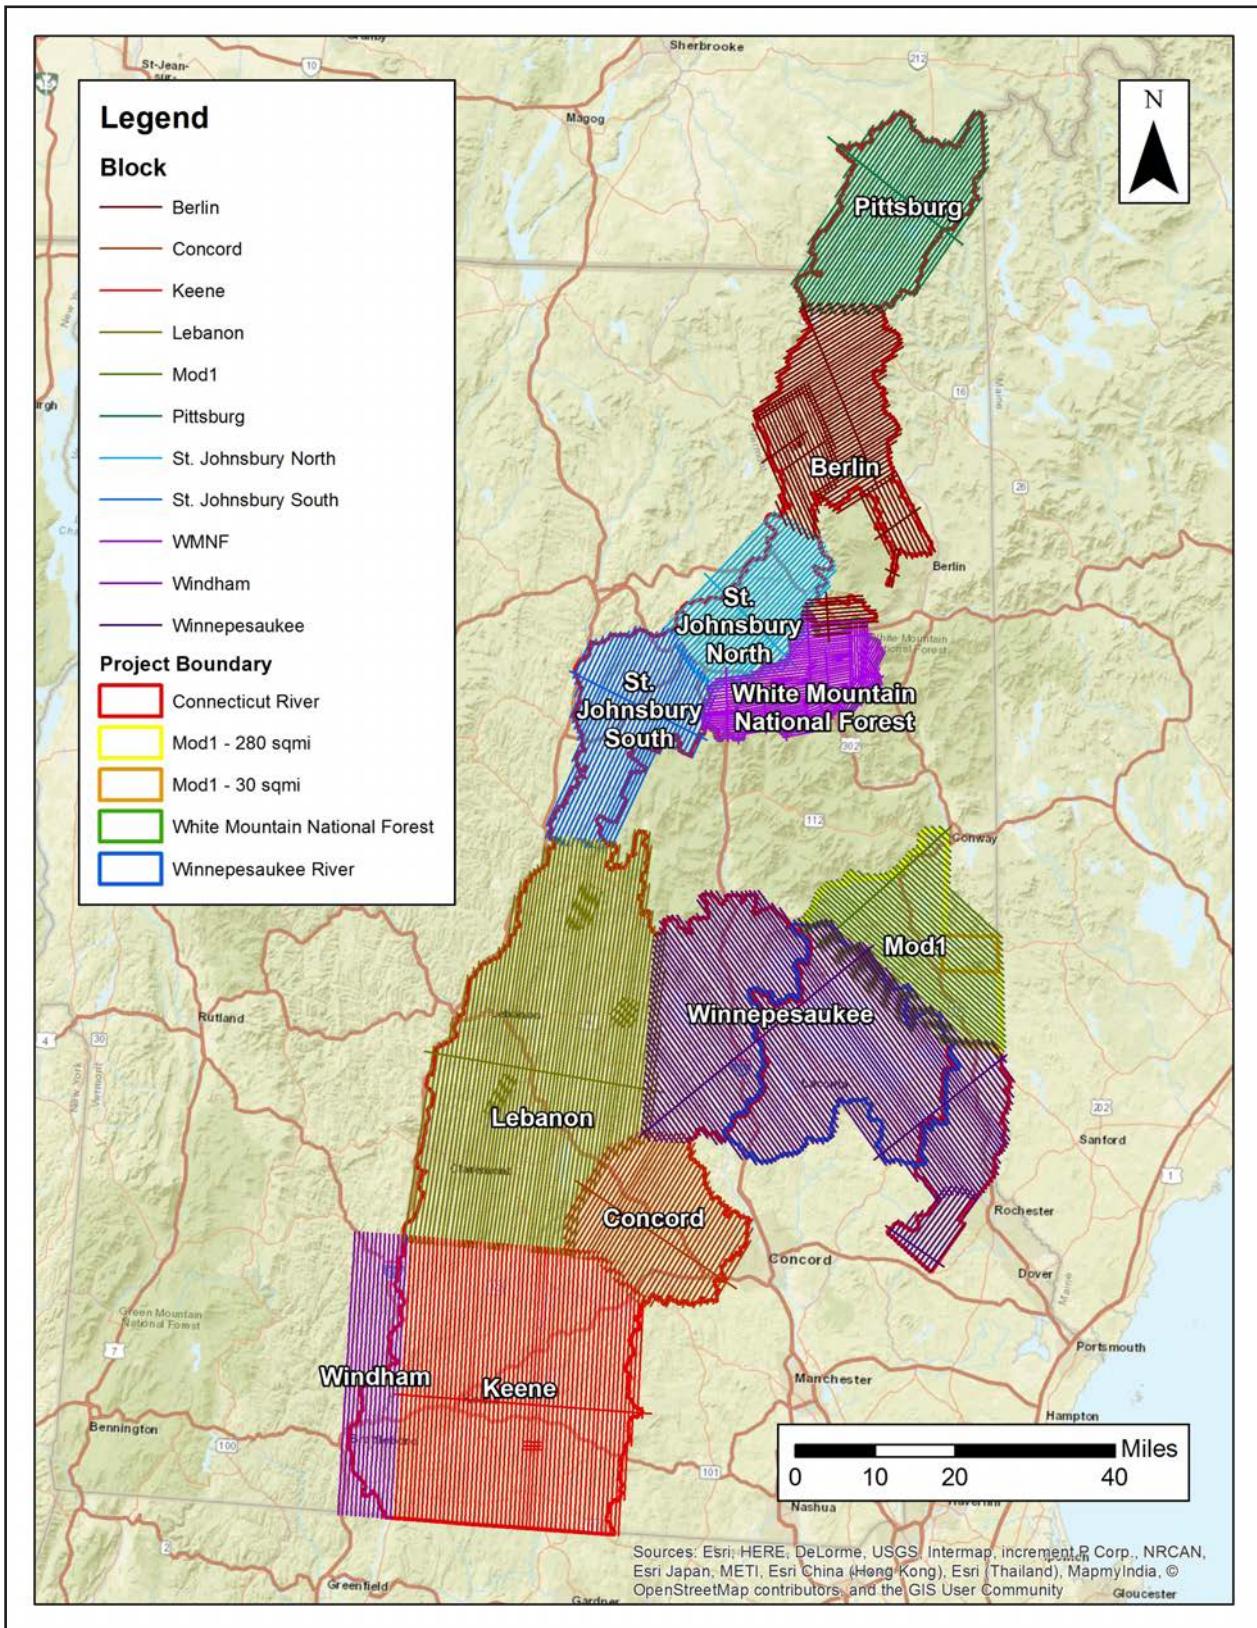

Flight planning was based on the unique project requirements and characteristics of the project site. The basis of planning included: required accuracies, type of development, amount / type of vegetation within project area, required data posting, and potential altitude restrictions for flights in project vicinity.

Detailed project flight planning calculations were performed for the project using Leica Mission Pro planning software. The entire target area was comprised of approximately 671 planned flight lines measuring approximately 12,869.24 total flight line miles (Figure 2).

### 2.2. LiDAR Sensor

Quantum Spatial utilized Leica ALS 70 LiDAR sensors (Figure 14), serial numbers 7161, 7178, 7169, and 7108, during the project. These systems are capable of collecting data at a maximum frequency of 500 kHz, which affords elevation data collection of up to 500,000 points per second. These systems utilize a Multi-Pulse in the Air option (MPIA). The sensors are also equipped with the ability to measure up to 4 returns per outgoing pulse from the laser and these come in the form of 1st, 2nd, 3rd and last returns. The intensity of the returns is also captured during aerial acquisition.

A brief summary of the aerial acquisition parameters for the project are shown in the LiDAR System Specifications in Table 2.

## 2.3. Aircraft

Quantum Spatial partnered with Precision Aerial Surveys and Woolpert, Inc. to collect data for this project. All flights for the project were accomplished through the use of the customized planes listed below.

### LiDAR Collection Planes

- Piper Navajo (twin-piston), Tail Numbers: N22GE, N6GR, N812TB
- Cessna 310 (twin-piston), Tail Number: N1107Q
- Cessna 206 Stationair (piston-single), Tail Number: N1107Q

These aircraft provided an ideal, stable aerial base for LiDAR and orthoimagery acquisition. These aerial platforms have relatively fast cruise speeds which are beneficial for project mobilization / demobilization while maintaining relatively slow stall speeds which proved ideal for collection of high-density, consistent data posting using state-of-the-art Leica ALS 70 LiDAR systems. Some Quantum Spatial's of the operating aircraft can be seen in Figure 15 below.

Figure 15. Some of Quantum Spatial's Planes

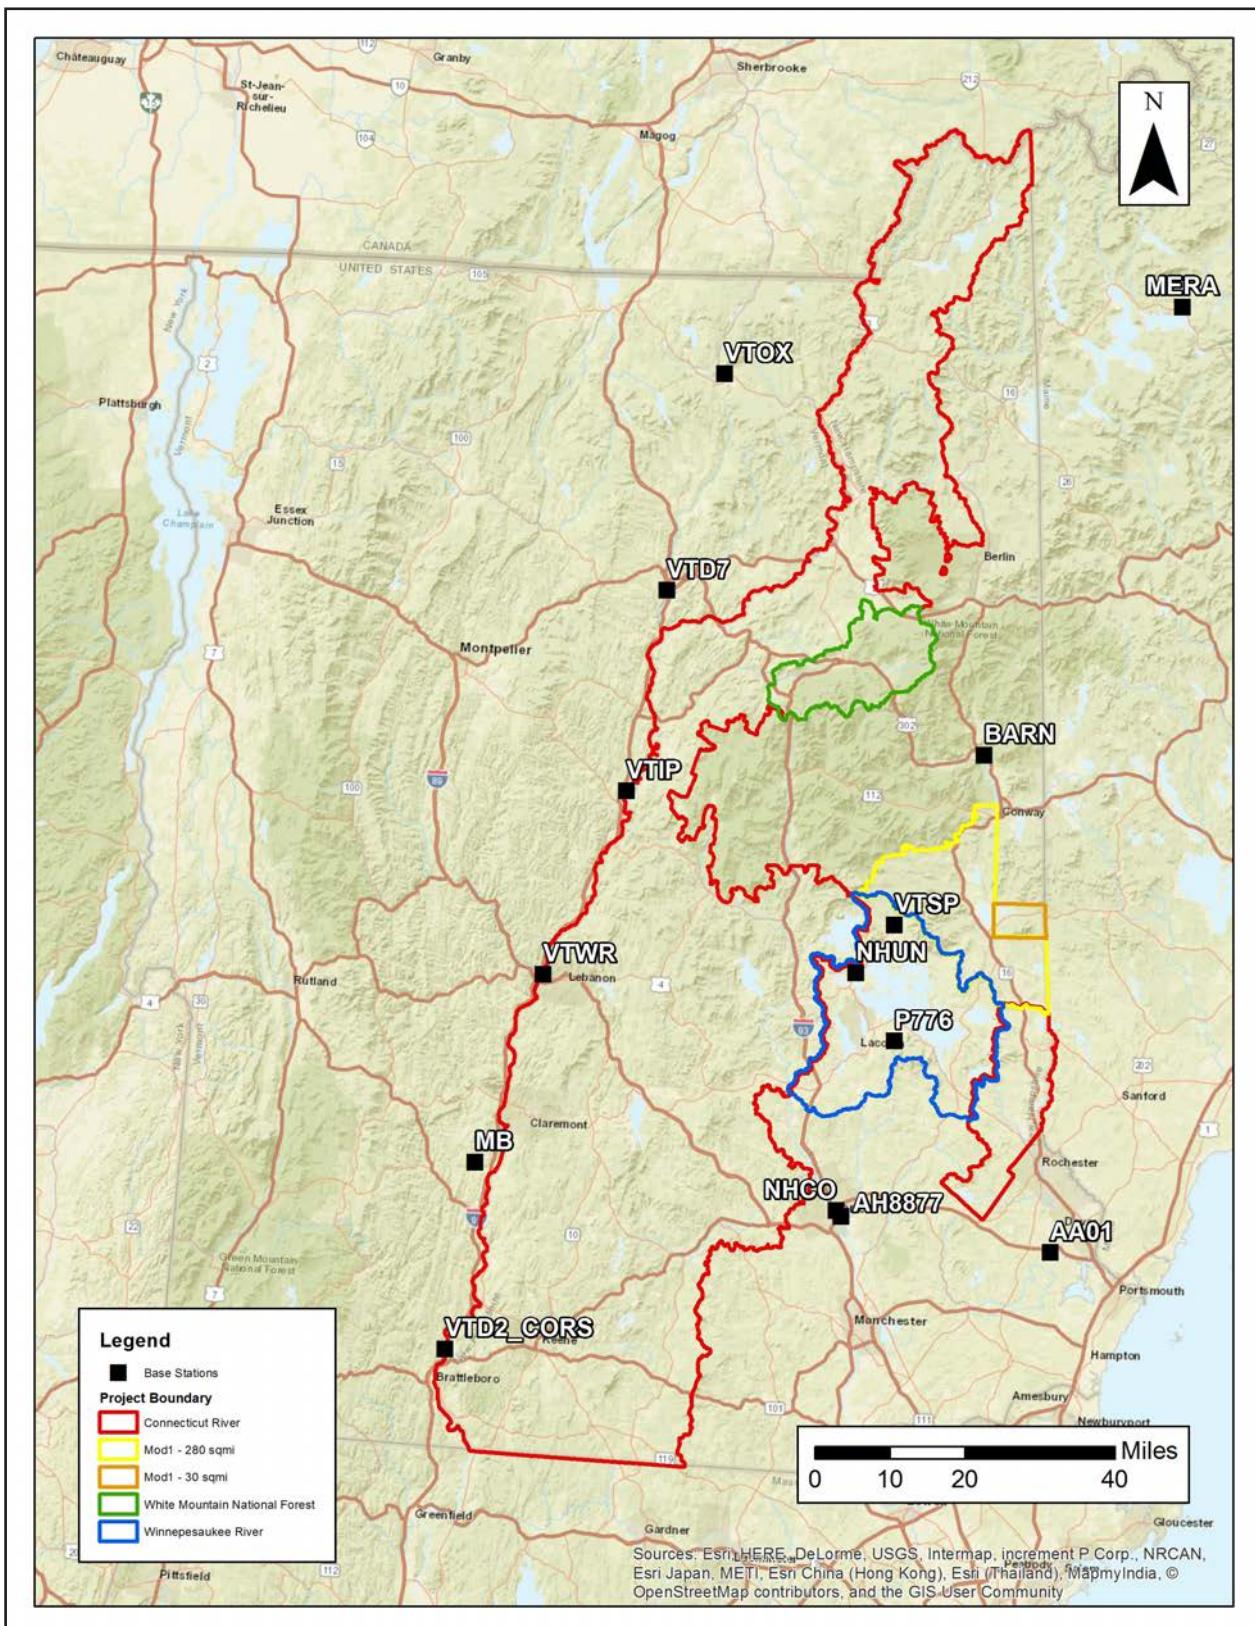

## 2.4. Base Station Information

GPS base stations were utilized during all phases of flight (Table 4). The base station locations were verified using NGS OPUS service and subsequent surveys. Base station locations are depicted in Figure 16. Data sheets, graphical depiction of base station locations or log sheets used during station occupation are available in Appendix A.

**Table 4. Base Station Locations**

Base Station	Latitude	Longitude	Ellipsoid Height (m)
MERA	44° 58' 25.33352"	70° 39' 10.58376"	489.568

## 3. Processing Summary

### 3.1. Flight Logs

Flight logs were completed by LiDAR sensor technicians for each mission during acquisition. These logs depict a variety of information, including:

- Job / Project #
- Flight Date / Lift Number
- FOV (Field of View)
- Scan Rate (HZ)
- Pulse Rate Frequency (Hz)
- Ground Speed
- Altitude
- Base Station
- PDOP avoidance times
- Flight Line #
- Flight Line Start and Stop Times
- Flight Line Altitude (AMSL)
- Heading
- Speed
- Returns
- Crab

Notes: (Visibility, winds, ride, weather, temperature, dew point, pressure, etc). Project specific flight logs for each sortie are available in Appendix A.

### 3.2. LiDAR Processing

Inertial Explorer software was used for post-processing of airborne GPS and inertial data (IMU), which is critical to the positioning and orientation of the LiDAR sensor during all flights. Inertial Explorer combines aircraft raw trajectory data with stationary GPS base station data yielding a “Smoothed Best Estimate Trajectory (SBET) necessary for additional post processing software to develop the resulting geo-referenced point cloud from the LiDAR missions.

During the sensor trajectory processing (combining GPS & IMU datasets) certain statistical graphs and tables are generated within the Inertial Explorer processing environment which are commonly used as indicators of processing stability and accuracy. This data for analysis include: Max horizontal / vertical GPS variance, separation plot, altitude plot, PDOP plot, base station baseline length, processing mode, number of satellite vehicles, and mission trajectory. All relevant graphs produced in the Inertial Explorer processing environment for each sortie during the project mobilization are available in Appendix A.

The generated point cloud is the mathematical three dimensional composite of all returns from all laser pulses as determined from the aerial mission. Laser point data are imported into

TerraScan and a manual calibration is performed to assess the system offsets for pitch, roll, heading and scale. At this point this data is ready for analysis, classification, and filtering to generate a bare earth surface model in which the above-ground features are removed from the data set. Point clouds were created using the Leica ALS Post Processor software. GeoCue distributive processing software was used in the creation of some files needed in downstream processing, as well as in the tiling of the dataset into more manageable file sizes. TerraScan and TerraModeler software packages were then used for the automated data classification, manual cleanup, and bare earth generation. Project specific macros were developed to classify the ground and remove side overlap between parallel flight lines.

All data was manually reviewed and any remaining artifacts removed using functionality provided by TerraScan and TerraModeler. Global Mapper was used as a final check of the bare earth dataset. GeoCue was used to create the deliverable industry-standard LAS files for both the All Point Cloud Data and the Bare Earth. In-house software was used to perform final statistical analysis of the classes in the LAS files.

### 3.3. LAS Classification Scheme

The classification classes are determined by the USGS Version 1.2 specifications and are an industry standard for the classification of LIDAR point clouds. All data starts the process as Class 1 (Unclassified), and then through automated classification routines, the classifications are determined using TerraScan macro processing.

The classes used in the dataset are as follows and have the following descriptions:

- Class 1 – Processed, but Unclassified – These points would be the catch all for points that do not fit any of the other deliverable classes. This would cover features such as vegetation, cars, etc.
- Class 2 – Bare earth ground – This is the bare earth surface
- Class 7 – Low Noise – Low points, manually identified below the surface that could be noise points in point cloud.
- Class 9 – In-lake Water – Points found inside of inland lake/ponds
- Class 10 – Ignored Ground – Points found to be close to breakline features. Points are moved to this class from the Class 2 dataset. This class is ignored during the DEM creation process in order to provide smooth transition between the ground surface and hydro flattened surface.
- Class 17 – Bridge Decks – Points falling on bridge decks.
- Class 18 – High Noise – High points, manually identified above the surface that could be noise points in point cloud.

### 3.4. Classified LAS Processing

The bare earth surface is then manually reviewed to ensure correct classification on the Class 2 (Ground) points. After the bare-earth surface is finalized, it is then used to generate all hydro-breaklines through heads-up digitization.

All ground (ASPRS Class 2) LiDAR data inside of the Lake Pond and Double Line Drain hydro

flattening breaklines were then classified to water (ASPRS Class 9) using TerraScan macro functionality. A buffer of 1 meter was also used around each hydro-flattened feature to classify these ground (ASPRS Class 2) points to Ignored ground (ASPRS Class 10). All Lake Pond Island and Double Line Drain Island features were checked to ensure that the ground (ASPRS Class 2) points were reclassified to the correct classification after the automated classification was completed. All bridge decks were classified to Class 17.

All overlap data was processed through automated functionality provided by TerraScan to classify the overlapping flight line data to approved classes by USGS. The overlap data was identified using the Overlap Flag, per LAS 1.4 specifications.

All data was manually reviewed and any remaining artifacts removed using functionality provided by TerraScan and TerraModeler. Global Mapper was used as a final check of the bare earth dataset. GeoCue was then used to create the deliverable industry-standard LAS files for both the All Point Cloud Data and the Bare Earth. Quantum Spatial proprietary software was used to perform final statistical analysis of the classes in the LAS files, on a per tile level to verify final classification metrics and full LAS header information.

### 3.5. Hydro-Flattened Breakline Creation

For the CT River and Winnipesaukee River AOIs, class 2 LiDAR was used to create a bare earth surface model. The surface model was then used to heads-up digitize 2D breaklines of inland streams and rivers with a 30 meter nominal width and Inland Ponds and Lakes of 2 acres or greater surface area.

Elevation values were assigned to all Inland Ponds and Lakes, Inland Pond and Lake Islands, Inland Stream and River Islands, using TerraModeler functionality.

Elevation values were assigned to all Inland streams and rivers using Quantum Spatial proprietary software.

All ground (ASPRS Class 2) LiDAR data inside of the collected inland breaklines were then classified to water (ASPRS Class 9) using TerraScan macro functionality. A buffer of 1 meter was also used around each hydro flattened feature. These points were moved from ground (ASPRS Class 2) to Ignored Ground (ASPRS Class 10).

The breakline files were then translated to Esri file geodatabase formats using ESRI conversion tools for the Connecticut and Winnipesaukee River Watershed areas of interest.

### 3.6. Hydro-Flattened Bare-Earth Raster DEM Creation

For the CT River and Winnipesaukee River AOIs, class 2 LiDAR in conjunction with the hydro breaklines were used to create a 1-meter Raster DEM. Using automated scripting routines within ArcMap, a GeoTIFF file was created for each tile. Additionally, a mosaic was created for the entire area of interest. Each surface is reviewed using Global Mapper to check for any surface anomalies or incorrect elevations found within the surface.

### 3.7. Bare Earth Raster DEM Creation

For the WMNF AOI, class 2 LiDAR was used to create a 1-meter Raster DEM. Using automated scripting routines within ArcMap, an Esri grid file was created for each tile. Each surface is reviewed using Global Mapper to check for any surface anomalies or incorrect elevations found within the surface.

### 3.8. Intensity Image Creation

For the CT River and Winnipesaukee River AOIs, GeoCue software was used to create the deliverable Intensity Images. All overlap classes were ignored during this process. This helps to ensure a more aesthetically pleasing image. The GeoCue software was then used to verify full project coverage as well. 1-meter TIF/TWF files were then provided as the deliverable for this dataset requirement.

## 4. Project Coverage Verification

Coverage verification was performed by comparing coverage of processed .LAS files captured during project collection to generate project shape files depicting boundaries of specified project areas. Please refer to Figure 17.

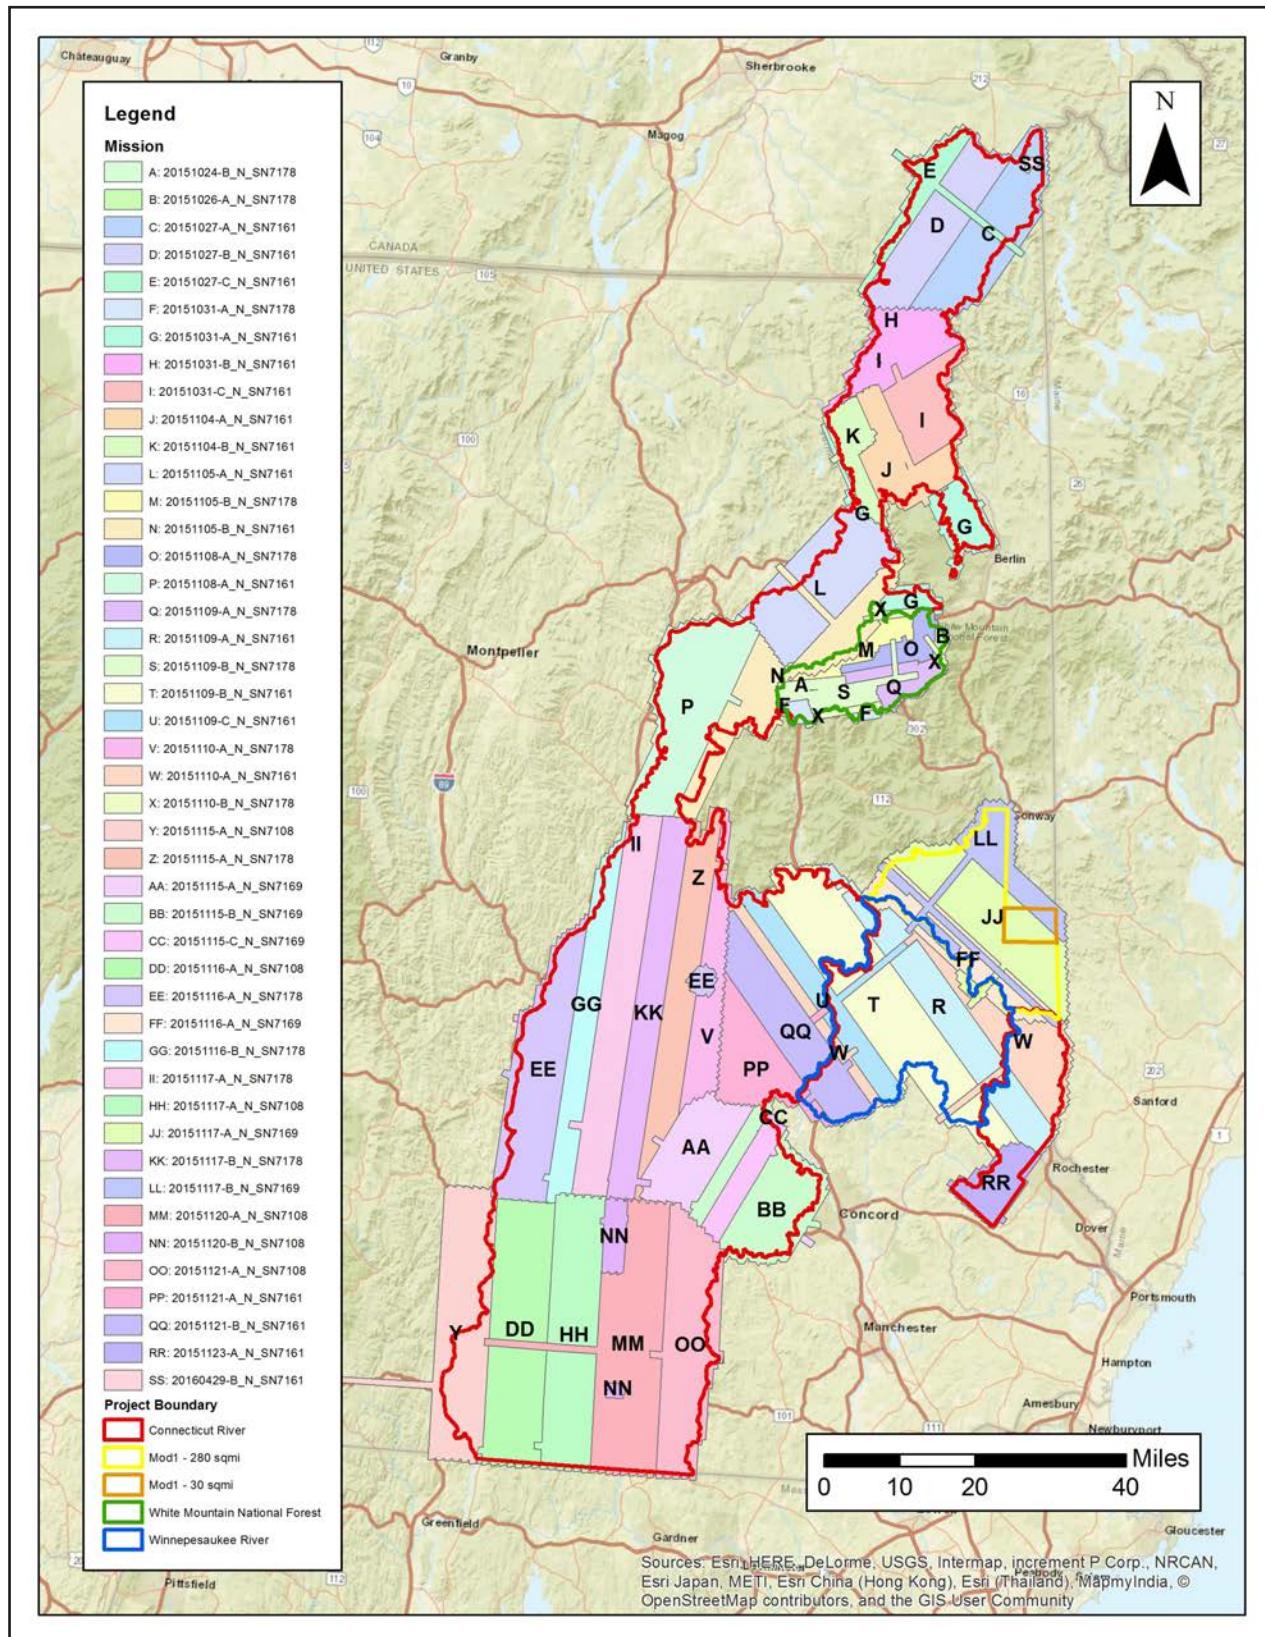

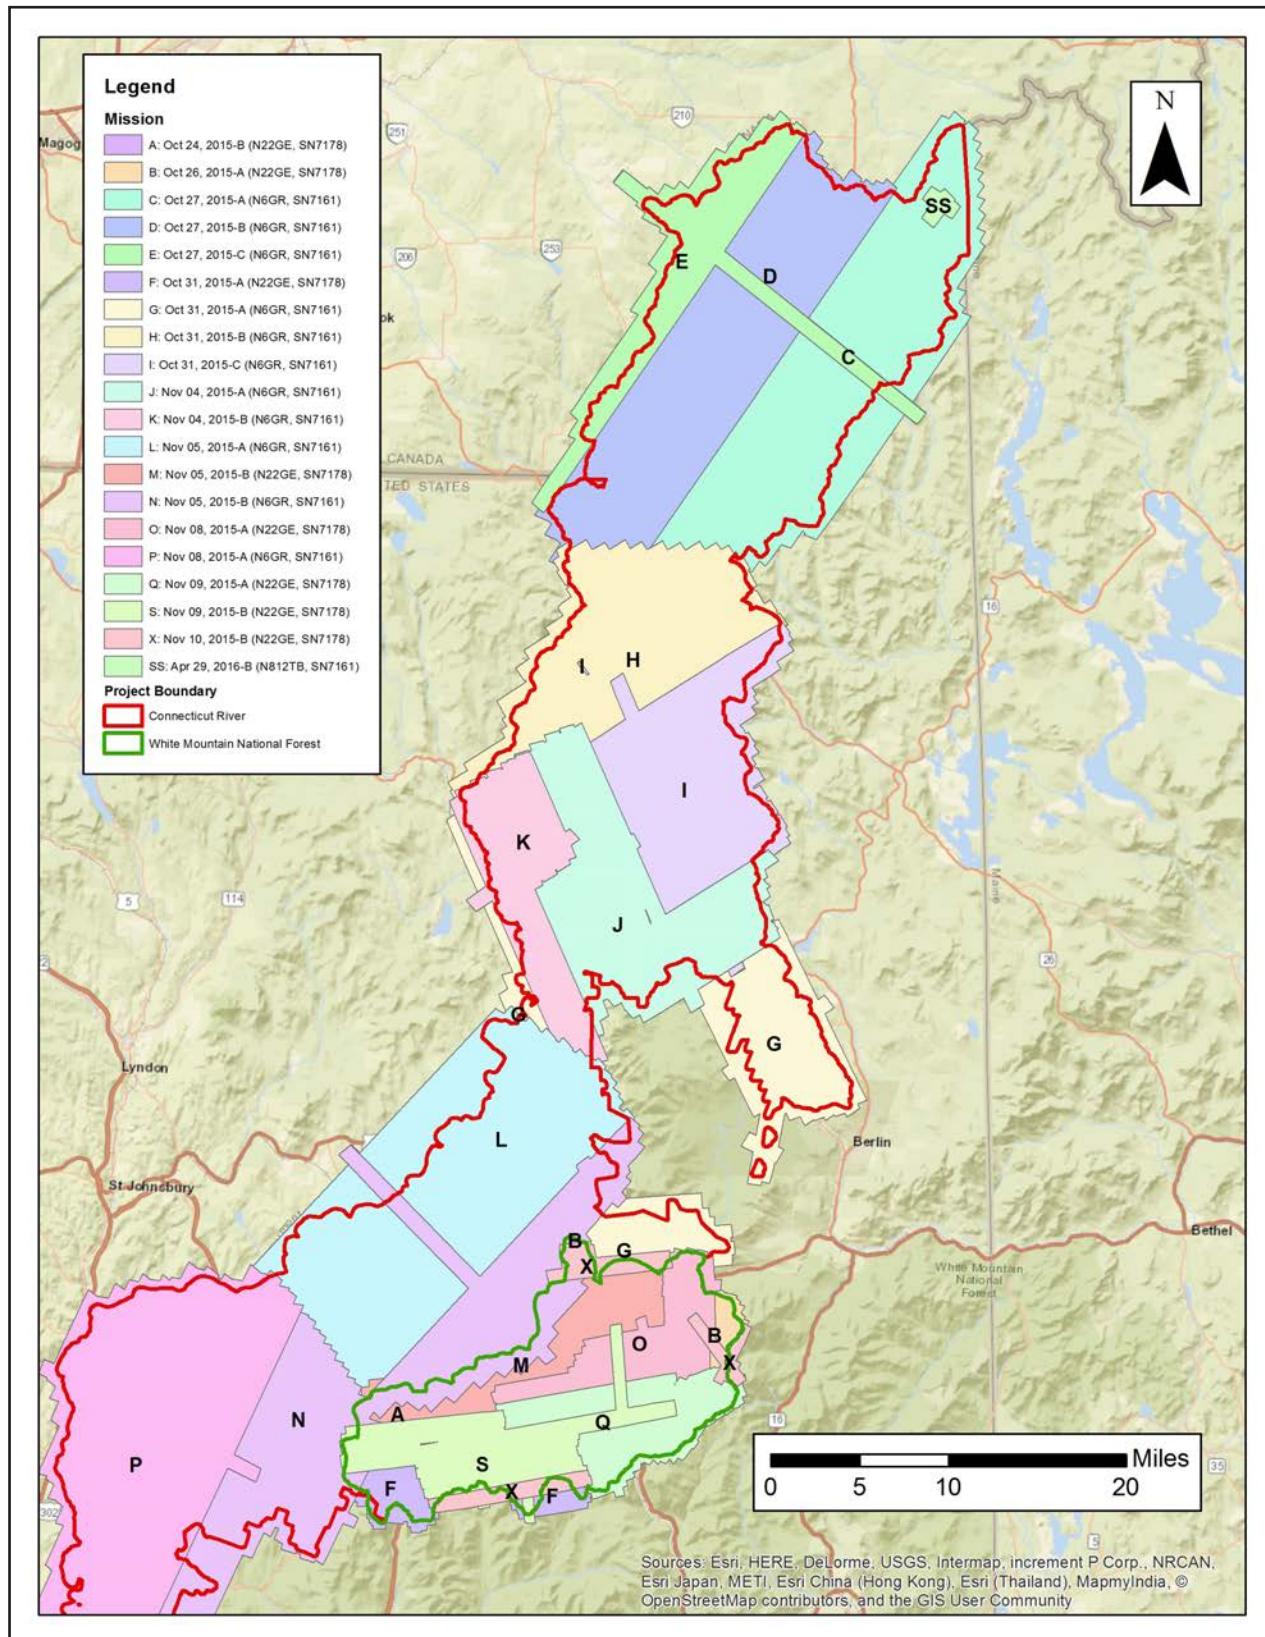

**Figure 17. Flightline Swath LAS File Coverage**

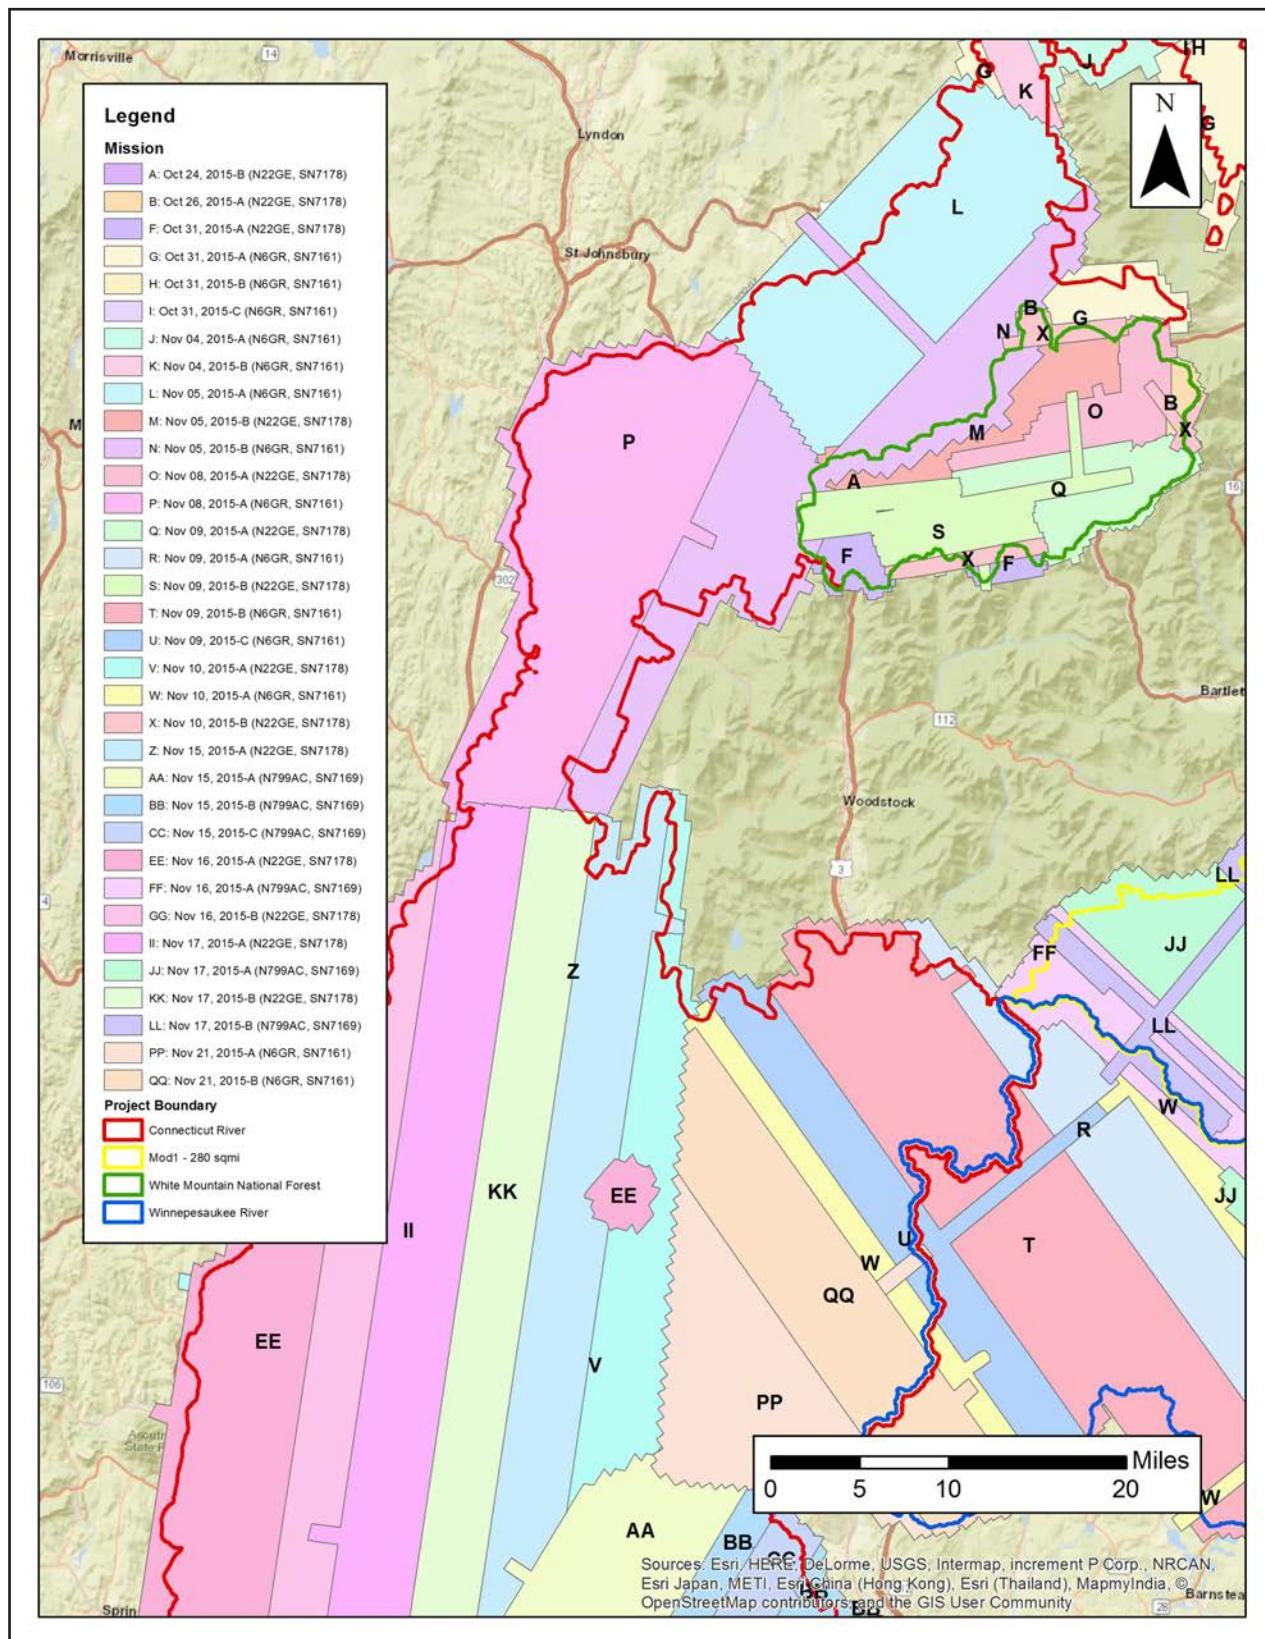

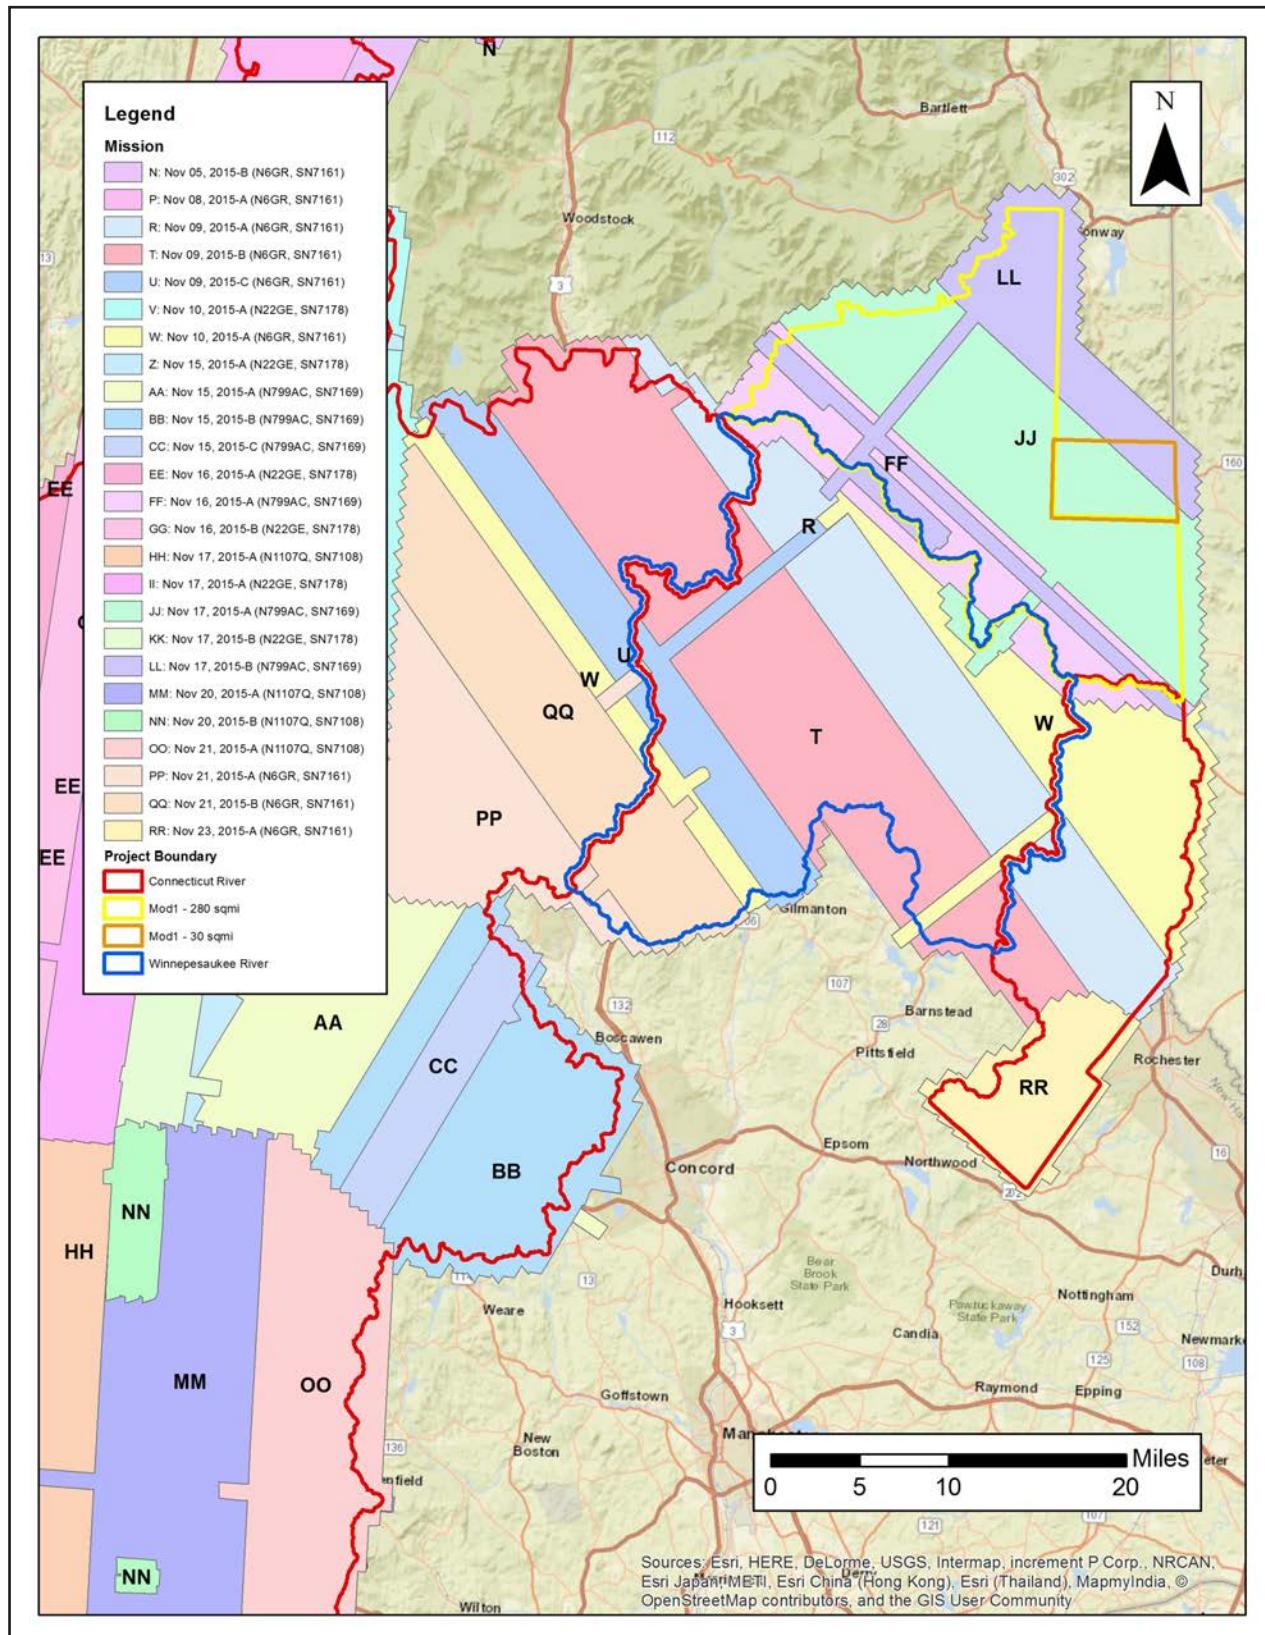

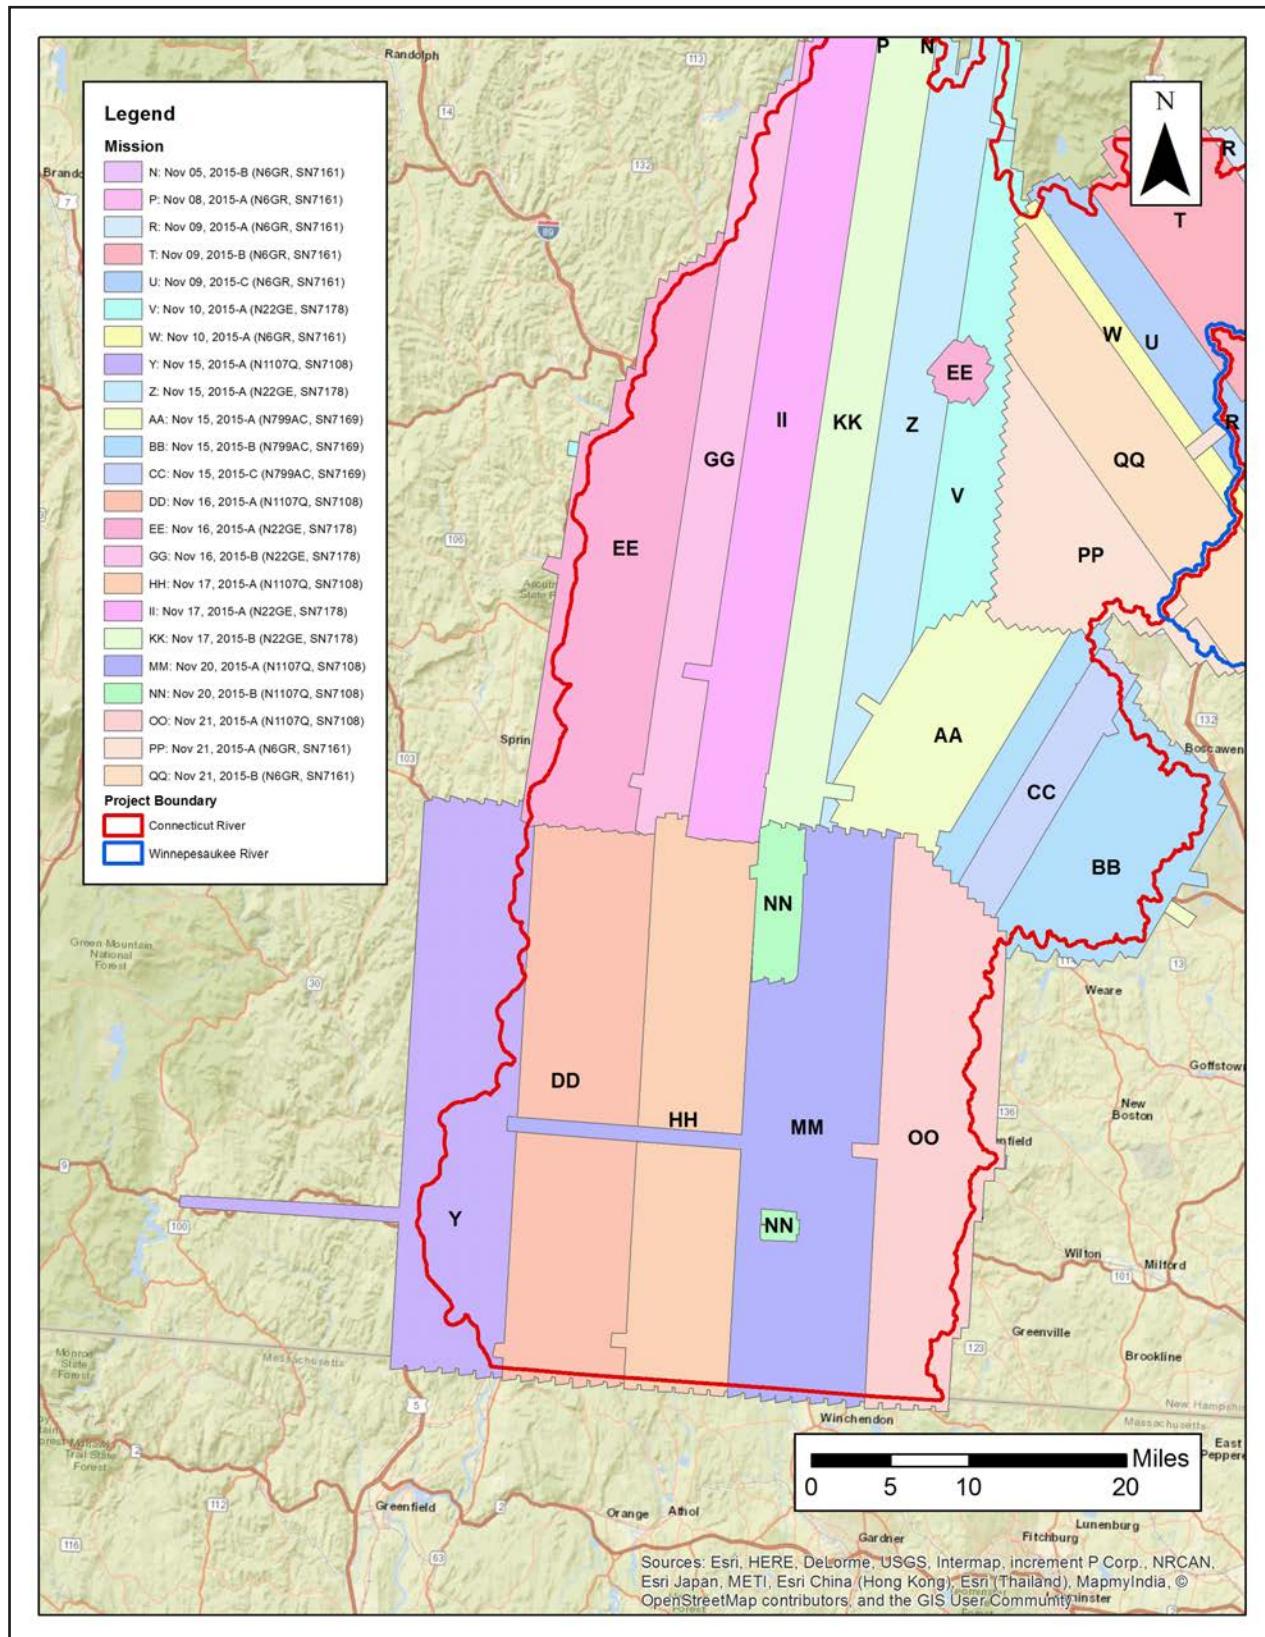

**Figure 19. Flightline Swath LAS File Coverage - Part 2**

Figure 20. Flightline Swath LAS File Coverage - Part 3

**Figure 21. Flightline Swath LAS File Coverage - Part 4**

## 5. Ground Control and Check Point Collection

Quantum Spatial completed a field survey of 155 ground control (calibration) points along with 252 blind QA points in Vegetated and Non-Vegetated land cover classifications (total of 407 points) as an independent test of the accuracy of this project.

A combination of precise GPS surveying methods, including static and RTK observations were used to establish the 3D position of ground calibration points and QA points for the point classes above. GPS was not an appropriate methodology for surveying in the forested areas during the leaf-on conditions for the actual field survey (which was accomplished after the LiDAR acquisition). Therefore the 3D positions for the forested points were acquired using a GPS-derived offset point located out in the open near the forested area, and using precise offset surveying techniques to derive the 3D position of the forested point from the open control point. The explicit goal for these surveys was to develop 3D positions that were three times greater than the accuracy requirement for the elevation surface. In this case of the blind QA points the goal was a positional accuracy of 5 cm in terms of the RMSE.

For more information, see the Survey Report in Appendix B.

The required accuracy testing was performed on the LiDAR dataset (both the LiDAR point cloud and derived DEM's) according to the USGS LiDAR Base Specification Version 1.2 (2014). In this document, horizontal coordinates for ground control and QA points for all LiDAR classes are reported in NAD83 (2011) UTM Zone 19, meters; NAVD88 (Geoid 12B), meters.

### 5.1. Calibration Control Point Testing

Figure 7 shows the location of each bare earth calibration point for the project area. Table 4 depicts the Control Report for the LiDAR bare earth calibration points, as computed in TerraScan as a quality assurance check. Note that these results of the surface calibration are not an independent assessment of the accuracy of these project deliverables, but the statistical results do provide additional feedback as to the overall quality of the elevation surface.

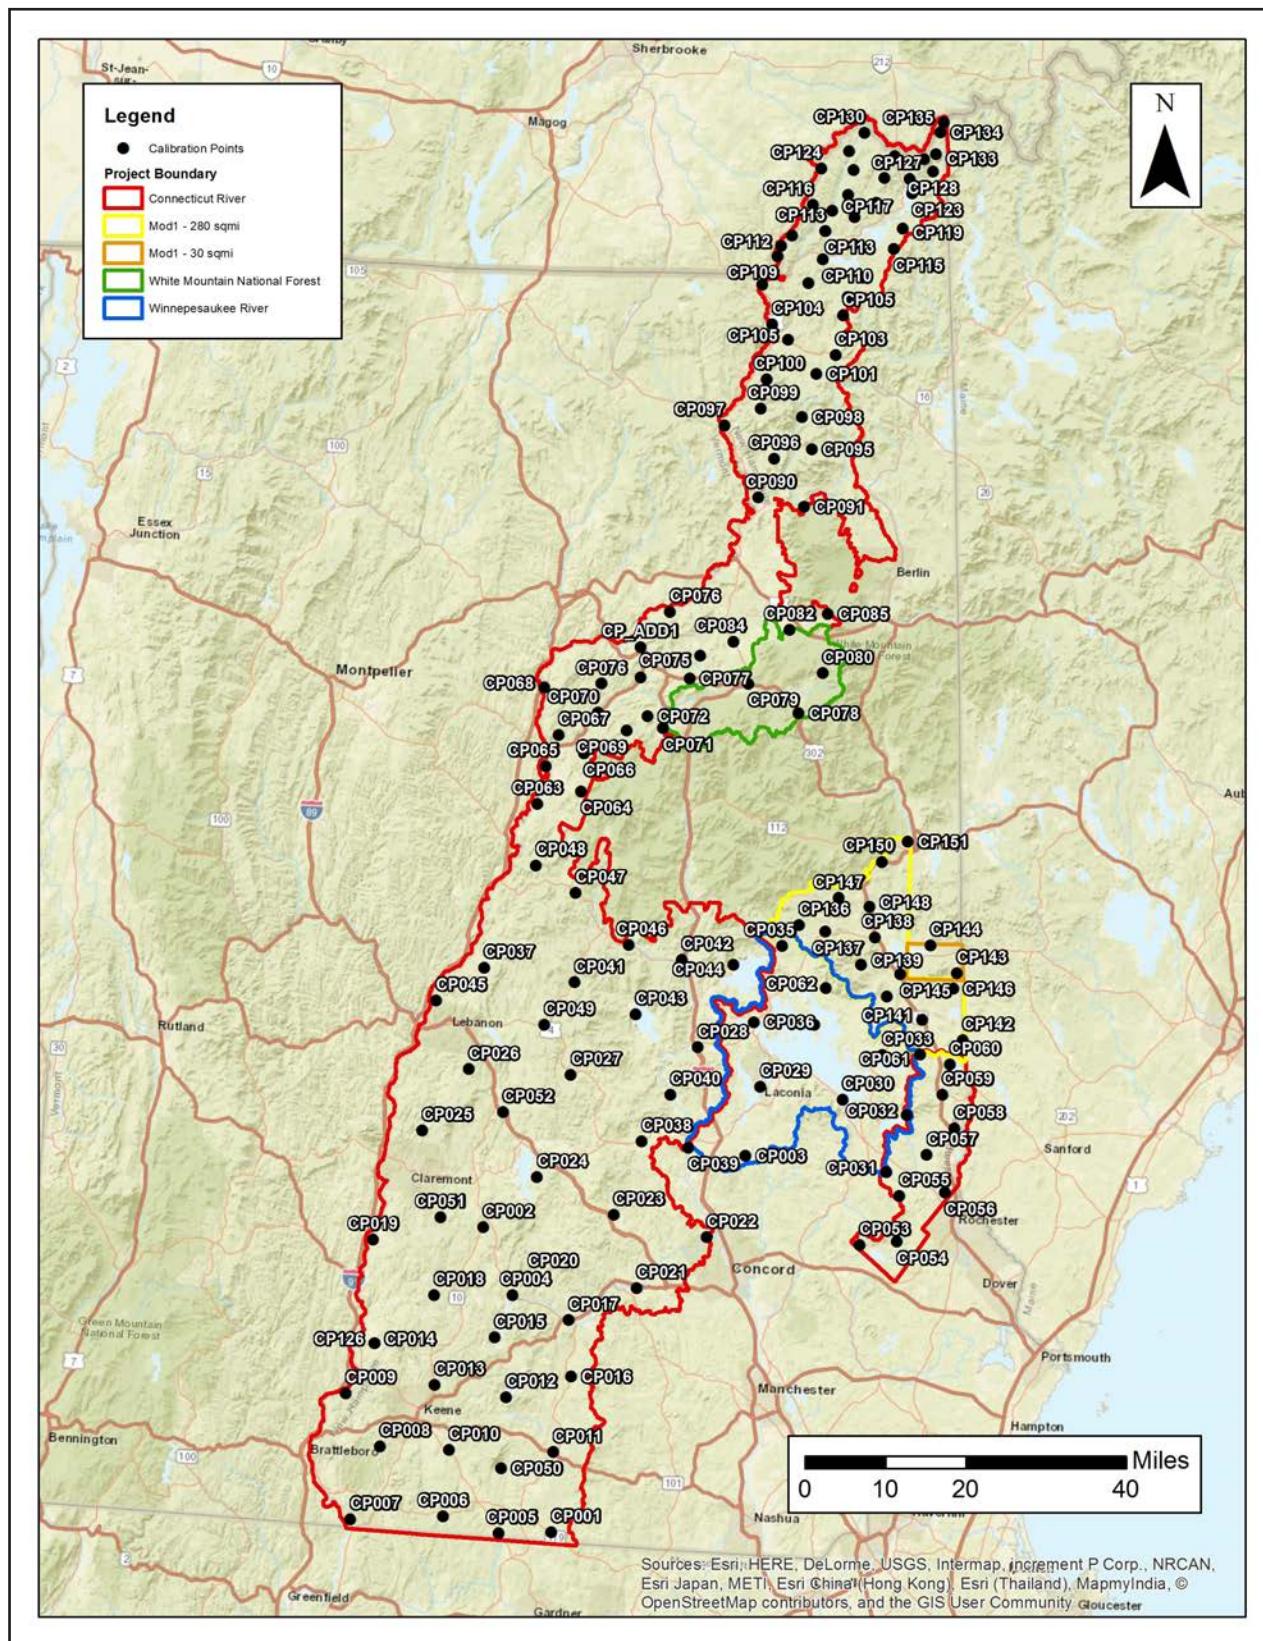

### 5.2. Point Cloud Testing

**Raw Nonvegetated Vertical Accuracy (Raw NVA):** The tested Raw NVA for the dataset was found to be 0.047 meters in terms of the RMSE<sub>z</sub>. The resulting NVA stated as the 95% confidence level ( $\text{RMSE}_z \times 1.96$ ) is 0.093 meters. This dataset meets the required FVA of  $\leq 0.196$  meters at the 95% confidence level (according to the National Standard for Spatial Database Accuracy (NSSDA)), based on TINs derived from the final calibrated and controlled LiDAR swath data. See Figure 8 and Table 5.

## 5.2. Digital Elevation Model (DEM) Testing

The tested Non-Vegetated Vertical Accuracy (NVA) for the dataset captured from the DEM using bi-linear interpolation to derive the DEM elevations was found to be 0.047 meters in terms of the RMSE<sub>z</sub>. The resulting accuracy stated as the 95% confidence level (RMSE<sub>z</sub> x 1.96) is 0.092 meters. This dataset meets the required NVA of 0.196 meters at the 95% confidence level (based on NSSDA). See Figure 9 and Table 6.

The tested Vegetated Vertical Accuracy (VVA) for the dataset captured from the DEM using bi-linear interpolation for all classes (including the bare earth class) was found to be 0.284 meters, which is stated in terms of the 95th percentile error. Therefore the data meets the required VVA of 0.294 meters. This test was based on the 95th percentile error (based on ASPRS guidelines) across all land cover categories. See Figure 10 and Table 7.
