## 1 Executive Summary

The primary purpose of this project was to develop a consistent and accurate surface elevation dataset derived from high-accuracy Light Detection and Ranging (LiDAR) technology for Allegany County, Maryland. The FEMA Region 3 FY 12 LiDAR project area encompasses 12 counties: Berkeley (WV), Clarke (VA), Fairfax (VA), Fauquier (VA), Frederick (MD), Frederick (VA), Jefferson (WV), Loudoun (VA), Morgan (WV), Washington (MD), Allegany (MD), and St. Mary/Golden Beach (MD). The deliverables, as required in the task order, are classified point cloud data (LAS), raw swath cloud data, hydro-flattened bare-earth DEMs, breaklines, metadata, and reports. This deliverable serves as the pilot deliverable for the FEMA Region III VA task order. This report documents the development of the deliverable products, including the planning, acquisition, and processing of the LiDAR data as well as the derivation of LiDAR products.

Dewberry served as the prime contractor for the project. In addition to project management, Dewberry was responsible for LiDAR classification, breakline production, DEM development and quality assurance. Dewberry's staff performed the final post-processing of the LAS files for the project, produced the breaklines used to enhance the LiDAR-derived surface, generated the 1 meter DEMs, and performed quality assurance inspections on all subcontractor generated data and reports. Geodigital performed the LiDAR data acquisition including data calibration. Their reports can be found in the Appendices.

This report covers the Allegany County deliverable.

# 2 Project Tiling Footprint and Coordinate System

The LiDAR delivery consists of five hundred and eighty five (585) tiles (Figure 1). Each tile's extent is 1500 meters by 1500 meters. This conforms to the Orthophotography and high-resolution elevation tile grid developed by the state of Virginia Geographic Information Network.

The projection information is:

Horizontal Datum: NAD83 Vertical Datum: NAVD88

Projection: UTM

Zone: 17N

Units (Horizontal & Vertical): Meters

Geoid: Geoid09

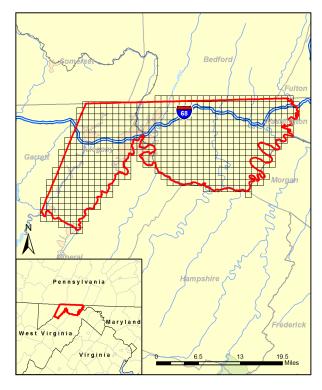

Figure 1 - Tile grid and project boundary of the Allegany area.

## 3 LiDAR Acquisition, Calibration and Control Survey Report

The LiDAR acquisition was completed in seven flight missions between January 29<sup>th</sup> and January 31<sup>st</sup>, and on February 3<sup>rd</sup> 2012. Geodigital provided a separate report documenting all of the steps in their acquisition process. That document can be found in Appendix A. Their report includes the LiDAR collection parameters, planned flight path maps, flight line trajectories, forward/reverse or combined separation plots, estimated position accuracy reports, and the flight log. Geodigital's Geodetic Control Survey Report (Appendix B) contains a thorough review of control used, including the final coordinates of the control, a map of the fully constrained control network, details of the constrained GPS network, new control station descriptions, and published control station descriptions. Geodigital's LiDAR Data Calibration Report (Appendix C) contains details of the LiDAR data processing and calibration as well as their vertical accuracy assessment (discussed below).

## 4 Vertical Accuracy Assessment

Geodigital verified internally prior to delivery to Dewberry that the LiDAR data met fundamental accuracy requirements (vertical accuracy NSSDA RMSEZ = 12.5cm, NSSDA AccuracyZ 95% = 24.5 cm) or better; in open, non-vegetated terrain) when compared to kinematic and static GPS checkpoints. Below is a summary for both tests:

The LiDAR dataset was tested to 0.1207m vertical accuracy at 95% confidence level based on consolidated RMSEz (0.04m x 1.960) when compared to 100 GPS static check points.

Dewberry further collected additional survey checkpoints and used those checkpoints to verify the accuracy of the LiDAR. Figure 2 shows the distribution of these check points throughout the dataset.

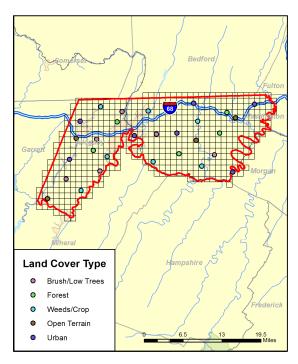

Figure 2 – Checkpoint Map shows that checkpoints are well distributed throughout project area.

Appendix A, Guidance for Aerial Mapping and Surveying, to FEMA's "Guidelines and Specifications for Flood Hazard Mapping Partners" requires a minimum of 60 test points -- 20 each in a minimum of three land cover categories representative of the floodplain. FEMA's Procedure Memorandum No. 61 – "Standards for Lidar and Other High Quality Digital Topography" -- specifies that the positional accuracy of LiDAR shall be in accordance with ASPRS/NDEP standards for accuracy testing as well as the USGS "Lidar Guidelines and Base Specifications, v13." All of these standards and guidelines require testing for Fundamental Vertical Accuracy (FVA), Supplemental Vertical Accuracy (SVA), and Consolidated Vertical Accuracy (CVA), using a minimum of 20 checkpoints each in a minimum of three land cover categories for a minimum total of 60 QA/QC checkpoints. Although tentative tests are performed on smaller subareas with fewer than 20 QA/QC checkpoints, Dewberry's final results will not be official until all areas are merged for testing of the total area with all project checkpoints.

The tables below show the vertical accuracy statistics and results. FVA (Fundamental Vertical Accuracy) is determined with check points located only in the open terrain land cover category (grass, dirt, sand, and/or rocks), where there is a very high probability that the LiDAR sensor will have detected the bare-earth ground surface and where random errors are expected to follow a normal error distribution. The FVA determines how well the calibrated LiDAR sensor performed. With a normal error distribution, the vertical accuracy at the 95% confidence level is computed as the vertical root mean square error (RMSEz) of the checkpoints x 1.9600. The second method of testing vertical accuracy, endorsed by the National Digital Elevation Program (NDEP) and American Society for Photogrammetry and Remote Sensing (ASPRS) uses the 95th percentile to report vertical accuracy in each of the other land cover categories (defined as

Supplemental Vertical Accuracy – SVA) and all land cover categories combined (defined as Consolidated Vertical Accuracy – CVA). The 95th percentile method is used when vertical errors may not follow a normal error distribution, as in vegetated terrain.

For Allegany County, the scope of work required the vertical accuracy to be NSSDA RMSE<sub>Z</sub> = 12.5 cm (NSSDA Accuracy<sub>Z</sub> 95% = 24.5 cm) or better; in open, non-vegetated terrain checked against the raw, swath LAS, classified LAS, and DEMs. The CVA is required to be NSSDA Accuracy<sub>Z</sub> 95% = 24.5 cm in both the classified LAS and DEMs. The following contains tables that list the RMSE checks for classified LAS, raw-swath LAS, and the digital elevation models.

#### **Classified LiDAR - RMSE Checks**

The RMSE<sub>Z</sub> is 0.13 meters in open terrain which slightly exceeds the project specifications of 0.125 meters for 5 survey points. The fundamental vertical accuracy is 0.26 meters which slightly exceeds the project specifications of 0.245 meters for 5 survey points. The consolidated vertical accuracy is 0.27 meters which meets project specifications of 0.363 meters (when compared with 30 survey points). Additional details and the supplemental vertical accuracy can be found in the tables below. While the Allegany dataset does not meet all of the individual RMSE requirements due to the very small number of ground survey points, we fully expect that when combined with the entire project area the RMSE requirements will be met.

Table 1 - Overall Descriptive Statistics for Checkpoints

100 % of Totals	RMSE <sub>z</sub> (m) Spec = 0.125 m <sup>1</sup>	Mean (m)	Median (m)	Skew	Std Dev (m)	# of Points	Min (m)	Max (m)
Consolidated	0.17	0.15	0.15	0.18	0.17	30	-0.02	0.32

#### Raw LAS Swaths - RMSE Checks

The RMSE<sub>Z</sub> is 0.14 meters in open terrain which slightly exceeds the project specifications of 0.125 meters for 5 survey points. The fundamental vertical accuracy is 0.27 meters which slightly exceeds the project specifications of 0.245 meters for 5 survey points. The consolidated vertical accuracy is 0.19 meters which meets project specifications of 0.363 meters (when compared with 30 survey points). Additional details and the supplemental vertical accuracy can be found in the tables below. While the Allegany dataset does not meet all of the individual RMSE requirements due to the very small number of ground survey points, we fully expect that when combined with the entire project area the RMSE requirements will be met.

Table 5 - Overall Descriptive Statistics for Checkpoints

100 % of Totals	RMSE <sub>z</sub> (ft) Spec=0.1 25m	Mean (m)	Median (m)	Skew	Std Dev (m)	# of Points	Min (m)	Max (m)
Open Terrain	0.14	0.13	0.12	-0.21	0.06	5	0.05	0.20

Table 6 - FVA value for Allegany County - Raw LAS Checks.

Land Cover Category	# of Points	FVA — Fundamental Vertical Accuracy (RMSEZ x 1.9600) Spec = 0.245 m
Open Terrain	6	0.27

As stated earlier, these RMSE results are preliminary and will not be official until all areas are merged for testing of the total area with all project checkpoints.

## 5 LiDAR Processing & Qualitative Assessment

## **5.1 LiDAR Classification Methodology**

The LiDAR is tiled into the 1500 m x 1500 m tiles named using the US National Grid tiling scheme. The data were processed using GeoCue and TerraScan software. The initial step was to setup the GeoCue project, which is done by importing the project defined tile boundary index. The acquired 3D laser point clouds, in LAS binary format, were imported into the GeoCue project and divided into tiles. Once tiled, the laser points were tested to ensure calibration accuracy from flightline to flightline. This check was done by creating a set of deltaZ ortho images. This process measured the relative accuracy between flight lines, or how well one flight line fits an overlapping flight line vertically. No issues were found during this step.

After these checks, the data was classified using a proprietary routine in TerraScan. This routine classified out any obvious outliers from the dataset, following which the ground layer was extracted from the point cloud. The ground extraction process encompassed in this routine takes place by building an iterative surface model. This surface model was generated using three main parameters: building size, iteration angle and iteration distance. The initial model was based on low points being selected by a "roaming window" with the assumption is that these are the ground points. The size of this roaming window was determined by the building size parameter. The low points were triangulated and the remaining points were evaluated and subsequently added to the model if they met the iteration angle and distance constraints. This process was repeated until no additional points were added within iterations. A second critical parameter was the maximum terrain angle constraint, which determined the maximum terrain angle allowed within the classification model.

Once the automated classification finished, each tile was imported into TerraScan and a surface model was created to examine the ground classification. Low lying buildings, porches, bridges, and small vegetation artifacts are often not caught during automated classification. These errors were inspected and edited during this step. Dewberry analysts visually reviewed the ground surface model and corrected errors in the ground classification, such as vegetation and buildings that are present following the initial processing. Dewberry analysts employed 3D visualization techniques to view the point cloud at multiple angles and in profile to ensure that non-ground points were removed from the ground classification.

After the ground classification corrections were complete, the dataset was processed through a water classification routine that utilized the breaklines compiled by Dewberry to automatically classify hydro features. The water classification routine selects points within the breakline polygon and automatically classifies them as class 9, water. The water classification routine also buffers the breakline polygon by 2 feet and classifies points with that buffered polygon to class 10, ignored ground for DEM production. The ground class for this data set is comprised of Class 2. Once the data classification was finalized, the LAS format 1.0 format points were converted to

LAS 1.2 Point Data Record Format 1 and converted to the required ASPRS classification scheme.

- Class 1 = Unclassified, and used for all other features that do not fit into the Classes 2, 7, 9, or 10, including vegetation, buildings, etc.
- Class 2 = Ground
- Class 7 = Noise
- Class 9 = Water
- Class 10 = Ignored Ground due to breakline proximity.
- Class 11 = Withheld

The following fields within the LAS files are populated to the following precision:

- GPS Time (0.000001 second precision)
- Easting (0.01 meter precision)
- Northing (0.01 meter precision)
- Elevation (0.01 meter precision)
- Intensity (integer value 12 bit dynamic range)
- Number of Returns (integer range of 1-4)
- Return number (integer range of 1-4)
- Scan Direction Flag (integer range 0-1)
- Classification (integer)
- Scan Angle Rank (integer)
- Edge of flight line (integer, range 0-1)
- User bit field (integer flight line information encoded)

The LAS file also contains a Variable length record in the file header.

Following the completion of LiDAR point classification, the Dewberry qualitative assessment process flow for the project incorporated the following reviews:

- 1. Format: Using TerraScan, Dewberry verified that all points were classified into valid classes according to project specifications.
  - a. LAS format 1.2, point data record format 1
  - b. All points contain populated intensity values.
  - c. All LAS files contain Variable Length Records with georeferencing information.
  - d. All LiDAR points in the LAS files are classified in accordance with project specifications.
- 2. Spatial Reference Checks: The LAS files were imported into the GeoCue processing environment. As part of the Dewberry process workflow, the GeoCue import produced a minimum bounding polygon for each data file. This minimum bounding polygon was one of the tools used in conjunction with the statistical analysis to verify spatial reference integrity.
  - a. No issues were identified with the spatial referencing of this dataset.

- 3. Data density, data voids: The LAS files are used to produce Digital Elevation Models using the commercial software package "QT Modeler" which creates a 3-dimensional data model derived from ground points in the LAS files. Grid spacing is based on the project density deliverable requirement for un-obscured areas.
  - a. Acceptable voids (areas with no LiDAR returns in the LAS files) that are present in the majority of LiDAR projects include voids caused by bodies of water. These are considered to be acceptable voids.
  - b. Dewberry identified no data voids within the dataset.
- 4. Bare earth quality: Dewberry assured the cleanliness of the bare earth during classification by removing all artifacts, including vegetation, buildings, bridges, and other features not valid for inclusion in the ground surface model.

## **5.2 LiDAR Processing Conclusion**

Based on the procedures and quality assurance checks, the classification conforms to project specifications set by the scope of work. All issues found during the qualitative QC were fixed. The dataset conforms to project specifications for format and header values. The quality control steps taken by Dewberry to assure the classified LAS meet project specifications are detailed below.

## 5.3 Classified LiDAR QA\QC Checklist

**Completion Comments: Complete - Approved** 

## 6 Breakline Production

## **6.1** Breakline Production Methodology

Dewberry used GeoCue software to develop LiDAR stereo models of the project area so the LiDAR derived data could be viewed in 3-D stereo using Socet Set softcopy photogrammetric software. Using LiDAR grammetry procedures with LiDAR intensity imagery, Dewberry stereo-compiled the five types of hard breaklines in accordance with the project's Data Dictionary. All drainage breaklines were monotonically enforced to show downhill flow. Water bodies were reviewed in stereo and the lowest elevation was applied to the entire waterbody.

## **6.2** Breakline Qualitative Assessment

Dewberry completed breakline qualitative assessments according to a defined workflow. The following workflow diagram represents the steps taken by Dewberry to provide a thorough qualitative assessment of the breakline data (Figure 3).

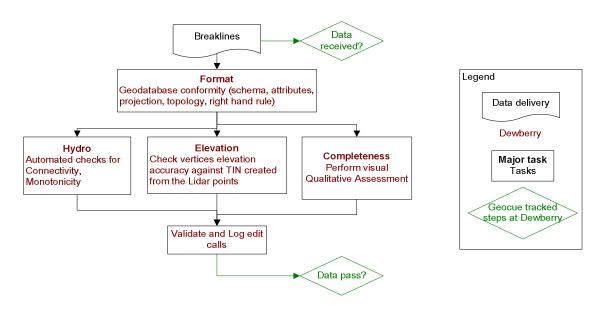

Figure 3 - Breakline Workflow

## 6.3 Breakline Topology Rules

Automated checks were applied on hydro features to validate the 3D connectivity of the feature and the monotonicity of the hydrographic breaklines. Dewberry's major concern was that the hydrographic breaklines have a continuous flow downhill and that breaklines do not undulate. Error points were generated at each vertex not complying with the tested rules and these potential edit calls were then visually validated during the visual evaluation of the data. This step also helped validate that breakline vertices did not have excessive minimum or maximum elevations and that elevations were consistent with adjacent vertex elevations.

The next step was to compare the elevation of the breakline vertices against the elevation extracted from the ESRI Terrain built from the LiDAR ground points, keeping in mind that a discrepancy is expected because of the hydro-enforcement applied to the breaklines and because of the interpolated imagery used to acquire the breaklines. A given tolerance was used to ensure that the elevations did not differ drastically from the LiDAR.

Dewberry's final check for the breaklines was to perform a full qualitative analysis. Dewberry compared the breaklines against LiDAR intensity images to ensure breaklines were captured in

the required locations. The quality control steps taken by Dewberry are outlined in the QA Checklist below.

## 6.4 Breakline QA/QC Checklist

#### Overview

- All Feature Classes are present in a geodatabase (GDB)
- All features have been loaded into the GDB correctly. Ensure feature classes with subtypes are domained correctly.
- The breakline topology inside of the GDB has been validated. See Data Dictionary for specific rules
- Projection/coordinate system of GDB is accurate with project specifications

#### Perform Completeness check on breaklines using either intensity or ortho imagery

- Check entire dataset for missing features that were not captured, but should be to meet baseline specifications or for consistency (See Data Dictionary for specific collection rules). NHD data will be used to help evaluate completeness of collected hydrographic features. Features should be collected consistently across tile bounds within a dataset as well as be collected consistently between datasets.
- Check to make sure breaklines are compiled to correct tile grid boundary and there is full coverage without overlap
- Check to make sure breaklines are correctly edge-matched to adjoining datasets if applicable. Ensure breaklines from one dataset join breaklines from another dataset that are coded the same and all connecting vertices between the two datasets match in X,Y, and Z (elevation). There should be no breaklines abruptly ending at dataset boundaries and no discrepancies of Z-elevation in overlapping vertices between datasets.

## **Compare Breakline Z elevations to LiDAR elevations**

Using a terrain created from LiDAR ground points and water points and GeoFIRM tools, drape breaklines on terrain to compare Z values. Breakline elevations should be at or below the elevations of the immediately surrounding terrain. Z value differences should generally be limited to within 1 FT. This should be performed before other breakline checks are completed.

#### Perform automated data checks using PLTS

The following data checks were performed utilizing ESRI's PLTS extension. These checks allowed automated validation of 100% of the data. Error records were either written to a table

for future correction, or browsed for immediate correction. PLTS checks should always be performed on the full dataset.

- Perform "adjacent vertex elevation change check" on the Inland Ponds feature class (Elevation Difference Tolerance=.001 feet). This check will return Waterbodies whose vertices are not all identical. This tool is found under "Z Value Checks."
- Perform "unnecessary polygon boundaries check" on waterbodies and Streams feature classes. This tool is found under "Topology Checks."
- Perform "duplicate geometry check". Attributes do not need to be checked during this tool. This tool is found under "Duplicate Geometry Checks."
- Perform "geometry on geometry check". Spatial relationship is contains, attributes do not need to be checked. This tool is found under "Feature on Feature Checks."
- Perform "polygon overlap/gap is sliver check". Maximum Polygon Area is not required. This tool is found under "Feature on Feature Checks."

#### **Perform Dewberry Proprietary Tool Checks**

- $\boxtimes$ Perform monotonicity check inland features using on streams "A3\_checkMonotonicityStreamLines." This tool looks at line direction as well as Features in the output shapefile attributed with a "d" are correct elevation. monotonically, but were compiled from low elevation to high elevation. These errors can be ignored. Features in the output shapefile attributed with an "m" are not correct monotonically and need elevations to be corrected. Input features for this tool need to be in a geodatabase. Z tolerance is .01 feet. Polygons need to be exported as lines for the monotonicity tool.
- $\boxtimes$ Perform connectivity check between (tidal waters to inland streams), (tidal waters to (inland ponds to inland streams) using inland ponds). "07 CheckConnectivityForHydro." The input for this tool needs to be in a geodatabase. The output is a shapefile showing the location of overlapping vertices from the polygon features and polyline features that are at different Z-elevation. The unnecessary polygon boundary check must be run and all errors fixed prior to performing connectivity check. If there are exceptions to the polygon boundary rule then that feature class must be checked against itself, i.e. inland streams to inland streams.

## Metadata

Each XML file (1 per feature class) is error free as determined by the USGS MP tool

Metadata content contains sufficient detail and all pertinent information regarding source materials, projections, datums, processing steps, etc. Content should be consistent across all feature classes.

**Completion Comments: Complete - Approved** 

## 7 DEM Production & Qualitative Assessment

## 7.1 DEM Production Methodology

Dewberry used ESRI software and Global Mapper for the DEM production and QC process. ArcGIS software was used to generate the products and the QC was performed in both ArcGIS and Global Mapper. The DEM workflow is shown in Figure 4 and described below.

Dewberry Hydro-Flattening Workflow

# Review LiDAR Review Breaklines Perform any necessary modifications to the LiDAR or Breaklines Classify ignored ground Classify water points using modified Breaklines Generate Terrain Using Create DEM zones for Proci Breaklines and LAS Convert Terrain to DEM Perform Initial QAQC Clip out individual Tiles Final Review for Edgematching Deliver DEM

Figure 4 – Dewberry's DEM Workflow

1. Classify Water Points: LAS point falling within hydrographic breaklines shall be classified to ASPRS class 9 using TerraScan. Breaklines must be prepared correctly prior to performing this task.

- 2. Classify Ignored Ground Points: Classify points in close proximity to the breaklines from Ground to class 10 (Ignored Ground). Close proximity will be defined as equal to the nominal point spacing on either side of the breakline. Breaklines will be buffered using this specification and the subsequent file will need to be prepared in the same manner as the water breaklines for classification. This process will be performed after the water points have been classified and only run on remaining ground points.
- 3. Terrain Processing: A Terrain will be generated using the Breaklines and LAS data that has been imported into ArcGIS as a Multipoint File. If the final DEMs are to be clipped to a project boundary that boundary will be used during the generation of the Terrain.
- 4. Create DEM Zones for Processing: Create DEM Zones that are buffered by 14m around the edges. Zones should be created in a logical manner to minimize the number of zones without creating zones to large for processing. Dewberry will make zones no larger than 200 square miles (taking into account that a DEM will fill in the entire extent not just where LiDAR is present). Once the first zone is created it must be verified against the tile grid to ensure that the cells line up perfectly with the tile grid edge.
- 5. Convert Terrain to Raster: Convert Terrain to raster using the DEM Zones created in step 4. Utilizing the natural neighbors interpolation method. In the environmental properties set the extents of the raster to the buffered Zone. For each subsequent zone, the first DEM will be utilized as the snap raster to ensure that zones consistently snap to one another.
- 6. Perform Initial QAQC on Zones: During the initial QA process anomalies will be identified and corrective polygons will be created.
- 7. Correct Issues on Zones: Corrections on zones will be performed following Dewberry's in-house correction process.
- 8. Extract Individual Tiles: Individual Tiles will be extracted from the zones utilizing the Dewberry created tool.
- 9. Final QA: Final QA will be performed on the dataset to ensure that tile boundaries are seamless.

## 7.2 DEM Qualitative Assessment

Dewberry performed a comprehensive qualitative assessment of the DEM deliverables to ensure that all tiled DEM products were delivered with the proper extents, were free of processing artifacts, and contained the proper referencing information. This process was performed in ArcGIS software with the use of a tool set Dewberry developed to verify that the raster extents match those of the tile grid and contain the correct projection information. The DEM data was reviewed at a scale of 1:5000 to scan for artifacts caused by the DEM generation process and to examine the hydro-flattened features. To perform this review, Dewberry created HillShade models and overlaid a partially transparent colorized elevation model. Upon completion of this review, the DEM data was loaded into Global Mapper to ensure that all files were readable and that no artifacts existed between tiles.

The quality control steps taken by Dewberry are outlined in the QA Checklist below.

## 7.3 DEM QA/QC Checklist

#### Overview

🛛 Correct number of files is delivered and all files are in IMG Format

All files are visually inspected to be free of artifacts and processing anomalies

DEM extent geometry shapefile is created

#### **Review**

All files are tiled with a 1 meter cell size

☐ Georeference information is populated and accurate

NAD\_1983\_UTM\_Zone\_17N

✓ Vertical accuracy is verified by comparing the LAS to the DEM

Water Bodies, wide streams and rivers and other non-tidal water bodies as defined in Section III are hydro-flattened within the DEM

Manually review bare-earth DEMs with a hillshade to check for processing issues or any general anomalies enforcement process or any general anomalies that may be present

**Completion Comments: Complete - Approved** 

## 8 Conclusion

Dewberry was tasked by the client to collect LiDAR data and create derived LiDAR products for Allegany County, MD. Geodigital was subcontracted to perform the LiDAR acquisition and calibration. Once Dewberry received the LiDAR data, initial QA/QC checks on the raw LAS swaths were performed. The LiDAR data were compiled to meet a vertical accuracy of 0.125 meters and, based on Geodigital's vertical accuracy tests and Dewberry's independently collected checkpoints, the data meets that criterion. The LiDAR data tested at 0.13 m vertical accuracy at 95% confidence level. The RMSE will not be official until all areas are merged for testing of the total area with all project checkpoints. Dewberry then classified the data according to project specifications and the classification was checked to ensure its accuracy. 3D breaklines were collected for the area. These breaklines and the LiDAR ground points were used to generate a DEM with hydro-flattened water bodies. Finally metadata were created for all deliverables. Based on the scope of work, all delivered products for the Allegany County, MD project conform to project specifications.
